GOOSEBERRIES (D. S.).—The Gooseberries are attacked by one of the rust fungi. These fungi have a rather curious life-history, for the spores which occur on the Gooseberry germinate and attack only Sedges. There is little good in spraying, but if the Sedges could be destroyed during the summer there would be no chance of the spores, which the fungus produces on them, being able to attack the Gooseberry in the spring. The most practical remedy would be to pick off and burn all the diseased Gooseberries as soon as the attack appears, and the leaves as well. The trouble is not usually a serious one.

MILDEW ON STRAWBERRIES (W. C.).—It is hopeless, we think, to try to free the plants so badly mildewed as are the sample leaves sent. The best way is to grub the plants up and plant fresh ones as soon as possible on well-manured and trenched land some distance away. Secure the strongest young plants you can get (and be sure they are free of mildew to start with). You will then have a heavy crop of fine-quality fruit next year. The only effective way of dealing with mildew on Strawberry plants is to watch closely for its first appearance in early spring, and then kill it with sulphur. If this is neglected until it has spread over most of the leaves, it is practically impossible to save the plants or the crops.

KITCHEN GARDEN.

TOMATOES SPLITTING (T. E. W.).—The splitting of Tomatoes is due to a sudden intake of water after a check. A plentiful supply of potash, which may be added in the water used for watering, is an aid towards checking the trouble.

POTATOES AND BLACK SCAB (L. A. H., Staffs).—The Potatoes are badly attacked by black scab or tumour.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

HERB GARDEN (E. M. G.).—We are not sure of your requirements. You speak of a "small effective herb garden," and seeing that the culinary herbs are difficult of effective treatment, we are wondering whether, when employing the shortened phrase "herb garden," you had in mind a herbaceous garden. Please kindly say.

KEEPING DAFFODILS AND TULIPS (R. W.).—Whether these will keep for another season depends not a little upon the way they have been treated. If the bulbs have been permitted to fully develop and ripen their foliage, and then lifted and dried for a time, there is no reason why they should not be just as good in 1913 as in 1912. If, on the other hand, the bulbs were lifted in an immature or growing state, it is highly probable that, while appearing sound, no flower-buds will be formed; hence, while producing quite healthy leaf-growth, no flowers would result in the coming year. Everything depends on the treatment meted out to the plants, and of this you tell us but little. If you desire a more definite reply, you must give fuller particulars. Lilac bushes require thinning rather than pruning, that is, the removal of small superfluous shoots or branches and the suppression of all the sucker-like stems that spring so abundantly from the base of the plants. If you do this and remove all old flower-trusses, you will be doing all that is necessary. If, on the other hand, you prune the plants as you would a Rose bush, it is highly probable that you will get no flowers at all in the ensuing spring.

ANTIRRHINUMS AND SWEET WILLIAMS (H.).—We are not sure whether you are referring to the old plants of these, but, if so, we think you would be well advised to discard them and raise young stocks from seedlings or cuttings. If you were to sow seeds of the above named quite early in July thinly on a slightly raised and sheltered border, the seedlings would most likely winter well and be available for planting in February or March. In lighter

French neighbours for many lovely Roses, but our British introductions will hold their own against any from foreign parts, and as regards French-grown plants they are, unfortunately, often tainted with red rust and other fungoid diseases, which will soon spread to other Roses in the garden.

FRUIT GARDEN.

CHERRIES SPLITTING (T. S. E. M.).—The cause of the Cherries splitting is the spell of warm weather we have recently had, coming after so much rain. The air with the extra heat becomes too humid for ripe stone fruit or fruit approaching ripeness. The splitting will cease as soon as the air becomes drier.

SPRAYING APPLES (T. M. H.).—It is not at all probable, if your Cox's Orange Apple was sprayed with the caustic wash at the proper season and of the proper strength, that any of the trouble shown by the foliage or the stem is due to its effects. The branch sent was badly cankered and, indeed, dead three parts of the way through. Such shoots should be cut out and the wounds painted with lead paint or with Stockholm tar.

APPLES DROPPING (Slavertan).—Your Apples are attacked by the Codlin maggot. The best remedy for killing the larvæ of this is to spray the trees in winter with caustic alkali wash. This will kill all insect pests it may come in contact with. The best time to apply it is the first week in February. It also cleanses the trees from moss growth. The wash is poisonous and of a burning nature, and the person spraying the trees must have his clothes and hands protected. It is made as follows: Dissolve 1 lb. of commercial caustic soda and 1 lb. of crude potash in water. When both are dissolved, mix the two well together, then add three-quarters of a pound of

You must at once notify the presence of the disease to the Secretary, Board of Agriculture, Whitehall Place, S.W., and the Board will instruct you how to proceed. There is no known cure.

BROAD BEANS (L. A. T.).—The peculiar purplish spots on the foliage of the Broad Beans are due to the attack of aphids, of which you speak. Aphids excrete a peculiar sugary fluid called honey-dew, and this apparently drops upon the leaves below the point of attack, and subsequently, as a consequence, the spots develop.

ONION FAILURE (Anxious).—It was fortunate you sent with your Onion plants a quantity of the soil. It is in that we look for the failure of your Onions planted out from under glass. The soil to hand was clayey, close, hard, wet, sour, and as unfit for Onion growth as could well be. It would seem as if it had been worked a good deal during the wet winter to bring it into such a state. We cannot see what you can well do now to make matters better. The soil needs worked into it a heavy dressing of fresh-slaked lime, also wood-ashes and plenty of fibre, which seems to be specially lacking. Above all things, another year do not work ground while it is wet. Leave it until in a fairly dry condition. You may try now the effects of liming well and hoeing, but the texture of the soil is indeed bad.

CABBAGE-ROOT MAGGOT (F. P. and Torquay).—The Cabbage-root maggot, which attacks all kinds of Cabbage, Kale, Turnips, Radishes, &c., is extraordinarily prevalent this year in many parts of the country, and is an extremely difficult pest to deal with. It is the grub of a blackish, two-winged fly, rather similar in appearance to the house-fly. It lays its eggs near the Cabbage root, and sometimes upon it, in May or June, and the grubs pupate in the soil, turning to flies after a short period, there being about three, perhaps four, broods during the year.

THE NEW CULINARY APPLE PADNALL SEEDLING. (Half natural size.)

Some success has attended watering along the roots with an emulsion of carbolic acid, made by dissolving 1 lb. of hard soap in one gallon of boiling water, to which is added one pint of carbolic acid, the whole being churned with a syringe until thoroughly emulsified, and then diluted with twenty times its bulk of water. Care should be taken not to touch the plants when watering. Nitrate of soda will sometimes prevent the flies from laying their eggs, and the American growers put a piece of card close to the soil round the plants so as to prevent the fly getting near.

HERB GARDEN (E. M. G.).—The effective arrangement of a herb garden would, to some extent, be governed by space, and grouping the subjects should be the order of the day. You do not say the space which you have at disposal, which is rather important. However, assuming it to be a square, oblong, or oval plot of ground, you cannot do better than arrange so graceful a plant as the Fennel in the centre, and contrasting groups—contrasting in habit and in colour—of Rosemary on either side; or, if you prefer variety, one group of Rosemary and another of Rue, whose glaucous leafage is most effective. At extreme ends of these groups, Balm should find a place, and according to the size of your plot these might include the central batch of groups, arranging them large or small according to the space at disposal. Fronting the Fennel, on either side you might arrange Sage, which, with its great mass of purplish flowers and grey green foliage, is one of the most striking plants of the garden. This plant should dominate in the positions indicated. Horneum and Wormwood are others of effective character to be quite removed from the last by a group of Mint, while for marginal plants you may indulge as freely as you will in Pennyroyal and common and Lemon Thymes in their green or variegated forms. As you have Lavender elsewhere, we omit this, and do not include the large number of such things as Parsley, Basil, Borage and the like so usually raised from seeds, and whose use in the circumstances would be entirely at your discretion.

MISCELLANEOUS.

BOOKS ON PRUNING (L. Anderson).—We think you would find "Rose Growing Made Easy," published from these offices, one of the most useful little books on Rose growing and pruning. For fruit tree pruning you could not do better than obtain "Fruit Growing for Beginners," also from these offices. The "Century Book of Gardening" is also a fine work for the amateur.

POTTING SOIL (F. V. H.).—It is preferable to allow the soil to stand a few days after Vaporite has been used before it is employed for potting purposes. At the same time, soil may be thoroughly disinfected by heating it over a fire in any way that may suggest itself. We do not think there will be any risk in using Vaporite in the way you mention, providing the instructions supplied with it are carefully carried out.

VARIOUS QUESTIONS (F.).—1. The grubs are the young larvae of the chafer. Birds will eat them if they can be turned up for them. A dressing of Vaporite, or some similar soil fumigant, would probably drive them away. Carbon bisulphide injected into the soil would kill them. 2. The curious growths on the *Rhododendron ferruginea* are galls caused by a fungus. They should be picked off and burned, lest the spores be spread. It is scarcely worth spraying, but potassium sulphide, 1 oz. to three gallons of water, might be used if it is wished. 3. Water with a little Clay's Fertilizer or other manure should be applied at intervals.

NAMES OF FRUIT.—C. V. P. Keene.—Beurré Hardy. —J. B. F.—Apples: 1, Hollandbury; 2, Cellini; 3, Hawthornden; 4, Winter Peach; 5, Lord Derby. Pears: 1, Ne Plus Meuris; 2, Beurré Diel; 3, Louise Bonne de Jersey; 4, Beurré Hardy. —H. A. Barclay.—Williams' Bon Chrétien. —J. H. B.—Apple Colonel Vaughan. —W. H.—30, Devonshire Quarrenden; 31, Reineette Grise; 32, Hawthornden. —A. M. S.—1, Williams' Bon Chrétien; 2, Pitmaston Duchess; 3, Marie Louise d'Uccle. —S. S. G.—1, Williams' Bon Chrétien; 2, Beurré d'Amanlis; 3, Beurré Hardy; 4, Green Pear of Yar; 5, Ne Plus Meuris; 6, Louise Bonne de Jersey. —Amateur.—11, Bergamotte Espere; 12, Conference.

NAMES OF PLANTS.—T. C. C.—1, *Asplenium Nidus* (Bird's-nest Fern); 2, specimen too immature to identify; 3, *Nephtrolepis exaltata*; 4, *Asplenium bulbiferum fragilis*; 5, *Aloe* species, and 6, *Gasteria* species (cannot name these in this condition); 7, *Achimenes coccinea*. —C. Larkin.—*Araujia sericeifera* (*Physianthus albens*). —W. H., Essex.—4, *Asplenium Nidus* (Bird's-nest Fern); 5, *Scelopendrium vulgare* (Hart's-tongue Fern); 6, *Quercus Ilex* (Holly Oak); 7, *Taxus baccata* (Yew); 10, *Stachys lanata*; 11, *Tanacetum vulgare* (Tansy); 13, *Galega officinalis*; 18, *Sempervivum* species; 19, *Sempervivum prealtum*; 27, *Alovia citriodora*; 29, *Centaurea montana*; 32, *Galega officinalis* variety *alba*; the remainder were not in a suitable condition for naming. —A. E. S., Ozon.—1, *Callitriche verna* (Water Starwort); 2, *Chara fragilis*; 3, *Potamogeton crispus*; 4, *Elodea* (*Anacardis canadensis* (Canadian Pondweed)); 5, *Potamogeton pectinatus*; 6, *Ceratophyllum* species; none of these weeds is harmful to fish, but the water should not be allowed to get too full of them. Raking the weeds out is the best way of keeping them under control. —Amateur.—1, *Clerodendron feditum*; 2, *Gazaia splendens*; 3, *Verbena crinoides*; 4, *Senecio Cineraria* Dusty Miller; 5, *Trigonium* species, cannot name without flowers; 6, *Lychnis coronaria*; 7, *Kerria japonica*; 8, *Achillea* *the Pearl*; 9, *Oenothera purpurea*; 10, *Galega officinalis*.

—A. P., Glastonbury.—*Browallia viscosa*. —J. B. F.—*Berberis thunbergii*. —A. J. V.—Tree Tomato, *Cyphomandra betacea*.

BOOKS.

Alpine Flora (continued from page V. August 10 issue).—The illustrations are excellent. They are all in colour, and number 178 drawings of individual plants, reproduced water-colour drawings of the living plant growing in its native habitat. The detail is marvellous. Where all are so good it seems invidious to specify, but plate 46, *Eryngium alpinum*, is a work of art. Plate No. 7, *Aquilegia alpina*, is another delightful piece of work that gives one the idea, as no other illustration I have ever seen of it has succeeded in doing, of the exquisite beauty of this alpine gem, and one could go on picking out gems throughout the whole collection. The backgrounds employed are somewhat unusual, but they have been chosen with an artist's eye to effect and to bring out the colouring of the flower depicted, and in this they succeed admirably. One or two plates are not good, but whether this is due to the heightened colour natural to their native haunts or to deterioration from growing the plants in less congenial atmosphere here, I cannot say; but *Soldanella alpina*, Fig. 131, appears to have pink flowers, whereas I have never succeeded in getting anything else than a mauve shade of blue; and the Grass of Parnassus (*Parnassia palustris*) as illustrated has a distinct pink tinge to the petal. I have never had it any other colour than white with greenish veins. *Rosa alpina* (Fig. 61) is a much brighter shade of colour than I have ever been able to get it. All these are doubtless correct, and the difference is probably due to the fact stated. The book is worth buying for the illustrations alone. The General Introduction follows, and is divided into three parts: (1) The Native Environment of Mountain Flora; (2) The Acclimatisation and Culture of Alpines; and (3) Alpine Gardens and Rockeries. All three are exceedingly interesting and well written, the last giving short descriptions of the best known of the English alpine gardens, such as Friar Park, Henley; South Lodge, Leonardslee; Batsford Park; Warley Place; Ruby Lonsdale, and others. The remainder of the book is taken up by descriptions of the species and their best-known varieties, and this has never been done quite so satisfactorily before. Altogether the book is one that can be recommended to all interested in alpine flora. —H. E. MOLYNEUX.

SOCIETIES.

GLASGOW CENTENARY SHOW.

WITH a view to the celebration of the centenary of the Glasgow and West of Scotland Horticultural Society, the directors arranged for a special show, for which handsome prizes were offered, and arrangements were made to hold this in the hall and marquees on the Luncheon Grounds, Glasgow, on September 4, 5 and 6. The place selected proved very suitable, and as a result of the effort a show of much more than usual merit was held. On the invitation of the directors, the president and council of the Royal Horticultural Society sent a deputation to visit the show, and they awarded several special prizes. The deputation consisted of Sir D. Morris, Sir H. Veitch, Mr. H. B. May, Mr. J. Hudson and Mr. A. J. Gaskell. The show was opened by the Countess of Glasgow in a graceful manner, and Sir D. Morris spoke on behalf of the deputation. Sir John Stirling Maxwell occupied the chair. The display of plants, cut flowers, fruit and vegetables was one of great excellence, though scarcely so large as at the show of 1911, held in the grounds of the Exhibition, but considerably larger than that of 1910.

The non-competitive trade exhibits were of special value, and keen interest was displayed in the splendid exhibits shown. Messrs. James Veitch and Sons, Limited, Chelsea, sent a magnificent display of plants, showing the high quality which characterises their exhibits. It was

composed of stove, greenhouse and other plants, and included Orchids, Crotons, new hybrid *Rhododendrons*, *Streptocarpus* and many other subjects of the most modern types. Royal Horticultural Society's gold medal.

Messrs. Sutton and Sons, Reading, exhibited a very fine and effective display of vegetables, flowers, &c., of their noted strains, which well deserved the awards given of the Royal Horticultural Society's gold medal and a similar one from the Glasgow Society.

Messrs. Dobbie and Co., Edinburgh, sent a grand display of cut flowers, among which Collarette and other Dahlias, Sweet Peas, Roses and other flowers were of grand quality and effectively displayed. The Collarette Dahlias and Sweet Peas attracted much notice. Royal Horticultural Society's cup and society's gold medal.

Messrs. Webb and Sons, Wordley, Stourbridge, set up a tasteful stand of vegetables and flowers, the whole surmounted by a temple-like dome of Sweet Peas. Gold medal and silver-gilt Banksian medal.

From Messrs. Austin and MacLean, Glasgow, there came two effective displays. One of these was a capital show of stove and greenhouse plants, the other comprising vegetables, cut flowers and other produce. Gold, silver-gilt Flora and silver Banksian medals.

Messrs. Hugh Diekson, Limited, Belfast, exhibited a splendid lot of Roses of various classes, admirably grown and staged. Silver-gilt Banksian medal.

Messrs. John Forbes, Hawick, Limited, sent a large exhibit of florists' and other cut flowers and bedding plants, including Pentstemons, Phloxes, Carnations, &c.

Adjoining this was a stand of hardy flowers from Messrs. Cunningham, Fraser and Co., Comely Bank, Edinburgh, in which Phloxes were very prominent. Silver Banksian medal.

Messrs. Clibrans, Altrincham, made a special feature of vegetables and cut flowers in their fine exhibit, showing their excellent strains to advantage. Gold and silver-gilt Knightian medals.

Mr. A. Jones, Killarney, showed a group of Gladioli of the most modern types, including the dicerent late-flowering sections. Silver Banksian medal.

An effective exhibit of Pentstemons and other florists' flowers, with excellent Cauliflowers, &c., came from Messrs. Williamson, Gemmel and Co., Glasgow.

No exhibit attracted more admiration than the glorious Begonias from Messrs. Blackmore and Langdon, Bath, whose flowers were presented in grand form and of wonderful size and colour. Gold medal and the Royal Horticultural Society's cup.

Mr. John Snellic, Busby, showed early Chrysanthemums, Dahlias, &c.

One of the most beautiful and interesting exhibits was that made by Messrs. H. B. May and Sons, Edminton, who made a notable display of choice Ferns. Royal Horticultural Society's cup.

Orchids were specially well represented by an exhibit from Messrs. Sander and Sons, St. Albans, who staged a grand lot of the newest hybrids and others of the highest worth.

Carnations of the newest and best types were exhibited by Messrs. Young and Co., Hatherley, Cheltenham (silver Banksian medal), and Messrs. W. Cutbush and Sons, Highgate, London.

Messrs. Malcolm Campbell, Limited, Glasgow, set up magnificent exhibits of fruit and plants. Gold medal and Royal Horticultural Society's cup.

Mr. W. Wells, Limited, Merstham, exhibited early Chrysanthemums, &c.

Other trade exhibits included plants and flowers from Mr. William Leighton, Glasgow; flower stands from Mr. A. Edwards; cut flowers and pot plants, &c., from Mr. D. G. Purdie, Glasgow (silver-gilt Banksian medal); plants, &c., from Messrs. Pringle and Alexander, Glasgow; lawn-mowers from Messrs. Ransomes, Ipswich; horticultural requisites from Messrs. A. Cross and Sons, Glasgow, and "Gardenalities" and other firms. Several first-class certificates and awards of merit were given.

The competitive classes were of great beauty, and showed, as a whole, keen competition. Unfortunately, the pressure on our space compels a brief report only.

Cut flowers, as usual at this show, were of great excellence. Pot plants were, as a whole, good, although rather limited. Fruit was very fine indeed, especially the Grapes, and vegetables were grand. Florists' work was also good, and the decorated tables made a good show in themselves.

For the group of plants 15 feet by 10 feet, the first prize, which carried with it a Veitch Memorial Medal, went to Mr. A. Knight, Brayton, with a magnificent group of very fine plants; second, Mr. J. E. Davies, Pallathie, with smaller plants, but a highly-tasteful arrangement.

Mr. Knight was also first for a circular group of plants, Mr. Davies occupying the same position as in the preceding class.

The first prize winners in the other plant classes included Mr. Knight, Mr. Davies, Mr. J. Templeton, Richmond House, Glasgow; Mr. A. McMillan, Douglas Castle; Mr. J. Swan, Lennoxton; Mr. J. Sutherland, Lenzie; Mr. D. Halliday, Ascog, Bute; Messrs. Malcolm Campbell, Limited, Glasgow; Mr. J. Thompson, Broomfield, Giffnock; Mr. C. Pattison, Linwood, Paisley; Mr. J. Wilson, Dunlirae, Kirkintilloch; Mr. T. Nelson, Rutherglen; Mr. A. Aitchison, Kilsyth; Mr. P. Wallace, Dumbarton; Mrs. T. Carlyle, Mr. J. Orr, Mr. W. Jenkins, Mr. A. Kelly and Mr. W. Virtue.

The cut-flower classes were of surpassing interest to many, and those for Sweet Peas and Roses drew most notice. In the Sweet Pea collection class victory lay with Mr. J. Fletcher, Auchincloth, Lanarkshire, with a magnificent lot clearly ahead in a strong class. It won for him the silver Flora medal of the Royal Horticultural Society. Second, Mr. J. Paul, Drumbrugh, Killbuck.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

NOTES OF THE WEEK.

Trials of Violas at Wisley.—The trial of Violas has this year been so successful, particularly in the late spring and early summer, that it has been suggested (and the Council have accepted the suggestion) that the trial should be continued in 1913 with a special view of the date of the flowering of the various varieties. Growers, amateur as well as trade, are therefore requested to send three rooted cuttings of each variety (old as well as new), so that they may be planted before the third week in October. Address by post, The Superintendent, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.

The Double-flowered Periwinkle.—We were reminded of this little-known plant, which is the double form of the small-flowered Vinca, a few days ago when visiting the nurseries of Messrs. George Bunyard and Co. at Maidstone. It has the same trailing habit as the type, but the leaves are of a more leathery texture and more pointed. The flowers are double and resemble very closely in appearance the well-known Parma Violet. It continues to flower for several months, and would make a useful and interesting plant for the more shaded parts of the rock garden or for edging pathways.

Sedum spectabile for September Effect.—The value of this well-known garden plant for bedding effects in the early autumn does not appear to be sufficiently appreciated. Its large flat heads of rosy purple flowers, borne at a uniform height, make an admirable groundwork for tall-growing plants such as late-flowering Gladioli, and the effect when the colours are well chosen is pleasing in the extreme. Moreover, the glaucous leaves of the Sedum, even before the flowers appear, render a pleasing effect in themselves. The improved variety known as Sedum spectabile atropurpurea is likewise well adapted for late summer and autumn beds.

Two Late-flowering Roses.—Two admirable Roses that are flowering well this September and deserve to be more widely known are Joseph Hill and M. Paul Lede. Both are Hybrid Teas, and are excellent when grown in bush form. The former bears superb blooms of an apricot tint, and the latter is a delightful Rose with ochre red flowers. It is remarkable that these two varieties were not more in evidence at the recent show held by the National Rose Society. M. Paul Lede was certainly included in some of the large groups of Roses, but Joseph Hill was hardly shown at all. Yet both are capital garden Roses, and their virtues are not easily overrated.

A Beautiful Autumn Bed.—At this season of the year, when the ordinary summer bedding plants have lost their pristine beauty, it may be interesting to record a very charming bed that

we noticed a few days ago. Last autumn this bed, which is a good-sized circular one in a lawn, had a large bush of Berberis Darwinii planted in the centre, and this was surrounded by Darwin Tulips. In course of time the Berberis died; but, instead of uprooting it, the owner, in April last, sowed seeds of Canary Creeper around it, and at the end of May planted African Marigold Lemon Queen between the Tulips. The Canary Creeper had covered the dead Berberis early in the summer, and during the autumn this and the Marigolds have made a glorious combination of pale yellow.

The National Sweet Pea Society.—The London Exhibition of 1913 will be held at the Royal Horticultural Hall, Westminster, on July 17. It is hoped that a Northern Provincial Exhibition may be arranged for the second week of August, 1913. The society's annual meeting will be held this year on October 17 at the Hotel Windsor, Victoria Street, Westminster, and will be followed by a conference.

An Interesting Fuchsia.—Fuchsia macrosemina and its various varieties form a group of showy shrubs during late summer and early autumn, for they bloom with the greatest freedom and continue in flower for a long while. In the South and West Counties they are familiar as bushes 6 feet to 8 feet high and as far through, but in the Midlands and North it is usual to treat them as herbaceous plants, cutting them to the ground each spring and relying on young shoots to produce the flowers. In this way good bushy plants 3 feet or so in height may be obtained, which are equally effective whether grouped in the shrubbery or planted in beds. No elaborate cultural details are necessary for the successful growth of these plants, for planted in any ordinary garden soil they succeed admirably, while a stock of plants is easily raised from cuttings.

Dahlia Kaiserin Augusta Victoria.—For garden decoration and cut-flower purposes this is one of the best Dahlias grown. The flowers are moderate in size, double and pure white. They are borne on stiff stems well above the foliage, the plants continuing to produce a profusion of blossoms till checked by frost. Being about three feet in height, it is particularly valuable for small gardens. Several excellent examples of the value of this Dahlia for massing may be seen at Kew, one bed in particular near the Cypress collection containing some two hundred and fifty plants. It belongs to the section styled the double decorative bedding varieties. As the name suggests, Kaiserin Augusta Victoria is of German origin, it being extensively grown as a commercial variety for wreaths and crosses. Unfortunately, one of the newer Paeony-flowered varieties also bears the name Kaiserin Augusta Victoria, which may cause confusion.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Sunburst.—I should like to have the opinion of others who have grown this Rose as to what they really think of it. I got two plants of it from the raisers, and have been very disappointed with it. It is a nice grower and a good-shaped flower, but my plants have never given me a flower approaching the colour described in the catalogue. When you look down among the petals you do certainly find a good colour, but it never shows naturally. To all appearances it is an inferior Mrs. Aaron Ward. Perhaps the season may have been against it, or it may need growing under glass in order to get it good; but as an outdoor Rose, so far, I have found it most disappointing. What is the opinion of other growers?—G. T. W. (See "Autumn Roses in London," p. 476.)

Early Chrysanthemum Crimson Polly.—If Crimson Polly retains its colour as shown at the Glasgow Show by Messrs. W. Wells, Limited, Merstham, it is likely to be one of the most popular of the early Chrysanthemums of the day. In Northern gardens Polly comes rather too yellow to please many, but Crimson Polly is not a flower which should lose its colouring in the Northern climate. It is of the colour called "crimson" in Chrysanthemum parlance, and is in every way a counterpart of Polly, except in the matter of colour. Mr. Wells, who is responsible for this fine variety, anticipates that it will be one of the most popular of these early Chrysanthemums, and its appearance thoroughly supports his forecast of its future. It was well shown at Glasgow, and attracted a good deal of notice among the many growers in that district, where the early Chrysanthemum is so justly popular.—S. A.

Success with Autumn-sown Sweet Peas.—Perhaps it may interest you to hear of the success of my autumn-sown Sweet Peas, especially as I attribute it in great measure to the advice given in the columns of THE GARDEN. They were raised in boxes in the open air, and planted out in their permanent quarters in a low-lying situation under a west wall the first week in January. They nearly all survived the severe frost which soon followed, and I cut the first blooms from them on May 29. Since then, up to the present time, they have flowered luxuriantly. For weeks I only allowed them to have threes and fours, and I cut quite a charming bouquet from them only last Saturday. They have been rigorously heed and fed on Plantoids, but not once watered, although the spring drought was exceptionally severe here. The seed was from Mr. W. J. Unwin. Every one germinated and came true to colour. I have grown them *entirely* myself, for this is a large place with only one gardener, who has no time to help me. I hope, by means of liberally manuring the ground, to be able to grow Sweet Peas in the same place again next year.—BURTON, *Sutton-at-Hone, Kent.*

Woolly Aphis on Auriculas.—Referring to the reply to "J. E." on Auriculas and woolly aphis, page 455, September 7, I should like to make a few remarks on the same. Judging by my own experience, if the aphides are cleared off as much as possible at repotting-time, and subsequently kept away from the surface of the soil, and especially from the collar of the plant, I have not found that they have to any extent seriously affected the health of the plant. The late Rev. F. D. Horner said: "It (the woolly aphis) is hardly likely that

it is there for any honest purpose, and yet we cannot say that it affects the general health of the plant." A pinch of Tobacco powder will keep the aphids at bay from the collar, and also from the young roots that show on the surface of the soil. Personally, I do not use the Tobacco powder, but have made several blowpipes from pieces of Bamboo cane, which I keep handy in my Auricula frames. These I use to blow off the aphides as soon as I see them. I have found this effectual for the purpose, and have not seen reason to change my practice. Our principal local grower, Charles Winn, Esq., of Selly Hill, has a very good grower in his head-gardener, Mr. T. Shepherd, who gave me a surprise a year or two ago by telling me that he used methylated spirit to rid his plants of the aphids, and that no injury to the plants accrued from its use. He said that in bad cases he had actually washed the roots in the spirit, and then put the plant on the potting-bench till dry, when he straightway potted it up. I have not tried this myself, but Mr. Shepherd has practised it for years. In repotting I use a medium stiff brush, and brush off all the aphides I can see. I am much pleased with the Auricula notes in THE GARDEN.—GEORGE J. SAVORY, *Birmingham.*

Roses with Bad Habits.—If every reader of THE GARDEN who takes more than a passing interest in growing Roses compiled a list of those varieties which he considered had bad habits, doubtless there would be unity of opinion concerning a great number; but there would also be, one feels sure, some difference of opinion about other sorts. The note by "C. B." on page 446, issue September 7, proves this point. Like "C. B.," I would absolve General Macarthur from being troublesome with mildew, but blame it for being so sparing with its flowers. In addition to the varieties branded by "P." under the above title, I will briefly mention a few more which, with us at least, have glaring faults. Ecarlate is a puny grower, and its flowers are small, petal-lacking specimens. True, it is bright and free, but, like Mrs. Tate and Betty, the flowers are so fleeting. The last two are lovely in the bud form, but they are past and gone almost before you have time to admire them. "P." mentions Mrs. S. Crawford as a bad mildewer. Yes, it is. And here are three other varieties which with us are equally bad, if at times not worse—Margaret Dickson, General Jacqueminot (otherwise so free and fragrant) and Mme. J. Grolez, added to which the latter is none too vigorous in growth. *Farbenkönigin* is also badly addicted to attacks of mildew. Marie Deleselle changes to a rather disappointing shade of colour; so does La France de '89; this passes to an undesirable bluish shade. The habit of growth characterised by Baroness Rothschild is bad, too besomified, or close. I think the worst offender we have for mildew in the pillar section is Una, worse than Crimson Rambler, practically all the flower-buds and stalks getting more or less tainted. But Una is worth retaining on account of its large flowers and its liberality in producing them. The Lyon we discarded because it was not sufficiently free.—C. T., *Higgate, N.*

—I am equally as astonished as "C. B." to notice that one of our correspondents condemns Rose General Macarthur for being liable to mildew. I have now grown it for several years, and have never found the least sign of mildew on it. If I had to name two Roses that were free from mildew, I should say General Macarthur and Rayon d'Or. No Rose gives more satisfaction in the garden than General Macarthur. For free growth,

abundance of flowers, splendid foliage and immunity from mildew, I hardly think it can be beaten.—G. T. W., *Bedale, Yorkshire.*

Crimson Hybrid Tea Roses.—I have read with interest the lists of Roses adversely criticised in your recent issues. Of the forty varieties, twelve are crimson-flowered, and of these eleven are crimson Hybrid Teas. Can your contributor recommend one or more crimson Roses for the garden which equal the pink Mme. Abel Chatenay in substance and constant succession of bloom? There are numerous beautiful Hybrid Perpetual crimsons, but I am at present unaware of any crimson variety that approaches many of the lighter-coloured Hybrid Teas in the constant succession of flowers.—RUBRUM. [At present we have not a crimson counterpart of Mme. Abel Chatenay among the Hybrid Teas. Liberty may perhaps be thought of by many Rose-growers to come very near to the ideal, but, unfortunately, its growth is not equal to Mme. Abel Chatenay. Leslie Holland and President Vignot are both fine novelties, and will doubtless take a leading part among our garden Roses; but at present General Macarthur seems to hold the field as the best all-round holding crimson. Laurent Carle is a superb Rose, but it lacks brilliancy. Lieutenant Chauré has been grand this year. It somewhat resembles a Hugh Dickson, with a dwarfer growth, but there is not quite the scarlet shading that we get in Hugh Dickson. It is, however, a good continuous bloomer of rather dwarf growth. Leuchtfeuer comes very near to our ideal, and Edward Mawley is a most continuous bloomer and very splendid at times, the fault being a tendency to "blue," which detracts from its general effect. I have a great opinion of Mrs. Edward Powell, but should rather try it another season before pronouncing definitely upon its merits.—DANECROFT.]

The Sporting of Californian-grown Sweet Peas.—In reference to the correspondence on this subject, pages 423 and 446, issues August 24 and September 7, there seems to be little doubt that Sweet Pea seed grown in America is not so true as that grown in this country. In many cases it appears probable that it is not so carefully and thoroughly rogued as English-grown seed; but there is another side to the question, and one of which I have seen no explanation. It is, I believe, a fact that stocks which have come perfectly true for some years on the raiser's land, when grown on other soils and under different conditions will break up in the most unexpected way. It is possible that the change of climate and soil causes sporting in the foreign seed. My own experience of Californian seed is unsatisfactory, and I find it difficult to get fixed stocks from it. At the same time, unless purchasers are willing to pay a higher price for English seed, it is difficult to see how they can be supplied with guaranteed English stocks. Take the last three seasons, 1910, 1911 and 1912; the first and last of these were exceptionally wet, and 1911 was remarkably dry. In 1910 there was practically no English seed available; in 1911 the crop, though excellent, was very short; and this year the wet weather of August has done much to destroy what would have been a splendid crop. Many English growers, in order to make sure of a sufficient supply of seed, send stocks over to California to be grown for them. It should not be impossible to grow all the seed required in this country at home, but purchasers would no doubt have to pay a slightly higher price at all times, and in exceptional seasons the fluctuations in price would be greater than at present.—T. H. DURNALL.

Roses in Town Gardens.—"A. P.," page 448, issue September 7, is quite justified in his assertion that fine Roses can be, and are, grown in the immediate suburbs of London. I have no doubt that beautiful blooms are grown in other parts, but I can testify to the fact that excellent Roses are grown in the Highgate and Finchley suburbs. At a recent show held there I saw some lovely blooms, including a bowl of the finest Mrs. John Laing I ever saw. In many gardens in that part Roses seemed to form one of the chief features.—G. G.

A Good Hardy Crinum.—In "Notes of the Week" in the issue for September 7 the reference to Crinum Powellii is very timely. In some of the gardens in and around Bournemouth, this variety and one or two others do very well indeed. The sandy soil seems to suit the plants remarkably well, favouring the necessary ripening essential to free-flowering conditions. In some rather low-lying parts, where there is constant moisture of the subsoil about four feet below the surface, these plants grow very strongly and bear large, well-coloured flowers. Just before the frosts come the surface of the soil is covered with short litter, which seems to afford the plants the needful protection.—B.

Campanula Zoysii.—It was with considerable interest that I read the note on Campanula Zoysii by "B., Weybridge," in your issue of August 10. It is pleasant to know that others find this charming little Campanula not only particularly interesting and quaint, but comparatively easy to grow. My plants have been especially attractive this year, as from the small rosettes of leaves the little flower-stalks rise some two inches to two and a-half inches high, and daintily arranged upon these are the curiously-shaped flowers. Not only are these blossoms constricted at their neck, but the flower is again almost closed at the mouth, seemingly never to open more than just sufficient to get a pencil point into it. It would be interesting to know the origin and use of this remarkable design. Here at Woodford the plant flourishes in my moraine, sending out underground runners, which cheerfully pierce their way between the stone chips, very much like a miniature version of C. Allionii. I am surprised that it thrives with your correspondent in so rich a compost as leaf-soil and loam, though the full southern exposure of which he speaks appears welcome by my plants also. My chief difficulty in growing it is to keep away the slugs and snails, to whom it appears very appetising. Possibly my midnight visitors have a special taste, but certainly I find that the flowers themselves of almost all the Campanulas are relished by them, so much so that C. isophylla (the pretty Ligurian Harebell), which is just now a charming inhabitant of my little alpine garden, forms quite a trap for them, and many may be caught therein by candle-light. The accompanying illustration gives, I think, a very fair idea of the dainty charm which this tiny Campanula displays as it shakes its pale blue bells in the August sunshine.—REGINALD A. MALBY.

FORTHCOMING EVENTS.

September 23.—National Chrysanthemum Society's Floral and Executive Committees' Meeting.

September 24.—Royal Horticultural Society's Meeting and Vegetable Show. Lecture by Mr. C. Hermann Senn on "How to Cook Some of the Root Vegetables."

THE ROSE GARDEN.

THE TWELVE BEST CLIMBING ROSES.

B EING asked the other day to name what I considered the twelve best climbing Roses, I named the following after a little hesitation. And now, after mature consideration, I still adhere to my selection. They are: 1, Mme. Alfred Carrière; 2, Climbing Caroline Testout; 3, Marie Bret; 4, Tea Rambler; 5, American Pillar; 6, Alister Stella Gray; 7, Leuchstern; 8, Morgenroth; 9, Blush Rambler; 10, Reine Olga de Wurtemberg; 11, Bouquet d'Or; 12, Thalia.

I have no doubt some, if not many, rosarians will disapprove of my selection. But I do not profess to be a rosarian, and certainly I am not an exhibitor; nor, were I to live to the age of Methuseleh, would I ever become an exhibitor.

No climber that I know, or have ever heard of, can surpass in these two characteristics the two I have placed first and second on my list. Marie Bret, No. 3, a Rose but rarely met with in English gardens, is very sweet and a fairly fragrant bloomer. It is a charming Rose, and quite a vigorous climber of a fine eoppery pink colour. The exquisite clusters of the Tea Rambler, No. 4, are well known to all Rose-lovers. The blooms are slightly fragrant, and though supposed to be only an early summer bloomer, I had two good blooms on one of my plants on August 21 of this year.

American Pillar, No. 5, so far as my experience goes, though almost scentless, begins to bloom about the middle of June, and was still in profuse and lovely bloom with me in the middle of July. Its bloom is so large and attractive, and produced in such grand clusters, that I have almost wished to give it a higher place in my list than No. 5, as its foliage is also so very good, and it is such a strong, vigorous climber.

CAMPANULA ZOYSII, A CURIOUS AUTUMN-FLOWERING SPECIES FOR THE ROCK GARDEN.

Yet I very much doubt if any exhibitor or rosarian is more fond of Roses than I am. And in a humble way, for my own delight and the pleasure of my friends, I can show a lot of really good Roses. My pergola in early summer is a glorious sight, and my espalier even now—in spite of wind and weather—is "a thing of beauty." I do not in the least care whether my Rose is of exhibition form, size and "petalage"—if I may be permitted to coin a term—but I do expect it to be, as I have said, "a thing of beauty" for the ordinary eye, and I do want it, if possible, to be a pleasure to the ordinary nasal organ. The longer any particular Rose will meet these two requirements, the more I am content. Therefore the two characteristics that have influenced me in the above selection of climbing Roses are fragrance and continuity of bloom. All our climbers, not forgetting the rambling form of the lovely but scentless Frau Karl Drusehki, are delightful to the eye so long as they are in bloom.

Alister Stella Gray, Leuchstern and Morgenroth, placed 6, 7 and 8 respectively, are almost perpetual bloomers with me throughout the summer. The first two are too well known to need description, but Morgenroth is not seen, I think, as often as it deserves to be. It is like Carmine Pillar, but the flower is larger and lasts longer, and when suitably established it climbs freely. No one who has ever seen the Blush Rambler, No. 9, in perfection can, I think, deny its right to be placed high in the list of climbing Roses, for though almost devoid of perfume, its enormous clusters are indeed a joy to behold.

Reine Olga de Wurtemberg, No. 10, is such a grand climber and gives such a profusion of lovely bloom while it lasts that I would have liked, if possible, to have given it a higher place in my list. One plant with me has taken to rambling all over an adjacent Apple tree, and was indeed a lovely sight in June. Bouquet d'Or, No. 11, is such a general favourite that I am sure I need not dilate upon its

merits. It is fragrant and blooms almost as constantly as *Alister Stella Gray*. *Thalia*, No. 12, is almost a perpetual bloomer, a strong climber, and its lovely clusters of small white blooms on my pergola have been immensely admired.

It will doubtless appear strange to many rosarians that I have given no place to such well-known and charming ramblers as our old friends *Turner's Crimson Rambler*, *Dorothy Perkins*, *Paul's Carmine Pillar*, *Bennett's Seedling*, *William Allen Richardson*, *Ards Rambler*, *Ards Rover*, *Hiawatha* and *Minnehaha*. Well, my reason is because they are all so short-lived in respect to bloom, and none of them when in flower is, in my opinion, as good as those I have chosen. Neither the *Crimson Rambler*, *Dorothy Perkins* nor *Carmine Pillar* is better than the *Tea and Blush Ramblers* or *Morgenroth*. *Bennett's Seedling* is very charming and sweet, but is not as perpetual a bloomer as *Thalia*, nor as sweet as *Mme. A. Carrière*. *William Allen Richardson*, though truly a lovely button-hole Rose and in some seasons a fairly continuous bloomer, is not as good in any way as *Alister Stella Gray*. *Hiawatha* and *Minnehaha* are very short-lived bloomers compared with *Leuchstern*, and neither of them is better in other respects. *Ards Rambler* and *Ards Rover I* certainly are a bit loth to leave out in the cold, for the former is sweet and the latter is certainly one of the best of our crimson ramblers, but not as good as *American Pillar*. *Tausendschön* is very good, but with me not really a vigorous climber. I hope these remarks of mine may call forth others
G. B. W.

AUTUMN ROSES IN LONDON.

THE National Rose Society's autumn exhibition, held in the Royal Horticultural Hall, Vincent Square, Westminster—a detailed report of which appears on another page—was one of the greatest surprises that rosarians have experienced during the present year. Owing to the prolonged wet and cold weather it was generally anticipated that mildew would have created havoc among the flowers; but, in the opinion of those best qualified to judge, the show was the finest that the society has ever held in autumn. A pleasing incident to many of the older members of the society was the presence during the early hours of the show of Mrs. Reynolds Hole, widow of the late Dean Hole, who for so many years acted as president of the society.

As indicative of the enormous strides that have been made in Roses during recent years, the exhibition was a great triumph. One had only to look through the various exhibits and note the prominence given to comparatively recently introduced Roses to get an idea of the extent to which our gardens have been enriched during the last decade by raisers in this and other countries. *Lyon*, *Lady Hillingdon*, *Irish Elegance*, *Harry Kirk*, *General Macarthur*, *Jessie*, *Miss Cynthia Forde* and *Frau Karl Druschki* easily held the best positions in all the large groups, yet ten years ago the majority were not in commerce.

Another surprising feature was the marvellous colour that was to be seen in many of the Roses. *Lady Hillingdon*, a most disappointing Rose in summer, was very beautiful in colour, the rich apricot yellow combining well in most instances with that glorious Rose *Lyon*. *Rayon d'Or*, in the few instances where it was shown, was exceedingly brilliant, and undoubtedly it is the coming yellow Rose for beds. It is a true yellow, the colour of the old Austrian Yellow, and is a bedding Rose quite by itself.

Mention of bedding Roses reminds us of the

secondary place that the exhibition Roses had to take on this occasion. By this we do not mean that they were of inferior quality. Mr. Hugh Dickson, Mr. George Prince and one or two other growers staged blooms of perfect quality, but for every visitor that found interest in them there were ten surrounding the beautiful vases and baskets of garden Roses, which shows the wisdom of the society in arranging classes for both sections. We suppose that exhibition Roses will always be with us, but there is no gainsaying the fact that, in the eyes of the general public, who, after all, form the supreme tribunal, they are of quite secondary importance compared with the free-flowering garden varieties.

Among the new Roses that received awards were two from the *Emerald Isle*, viz., *British Queen* and *Mrs. Charles Pearson*. These came from Messrs. McGredy and Son of Portadown, raisers who have won high honours in the lists of the society for several years past. The first-named, which is a large, full, creamy white Hybrid Tea, received a silver-gilt medal last year, and on this occasion was granted the more coveted gold medal. This high honour also went to *Mrs. Charles Pearson*, which is a glorified *Lyon* in colour, but in shape more resembles *Arthur R. Goodwin*. It is a beautiful Rose, very free flowering, and the blooms retain their exquisite colouring to the last. A gold medal also went to *Sunburst*, as grown under glass. This is undoubtedly a superb apricot yellow Rose for forcing, but the flowers come very pale outdoors. Another beautiful Rose of M. Pernet-Ducher's raising, but which did not get an award owing to the limited quantity shown, was *Willowmere*. It is a long, pointed Rose, somewhat after the colour of *Lyon*, but with much more pink diffused through the petals. Messrs. George Paul and Son, Cheshunt, had two new varieties on show, one being *Little Dorrit*, a beautiful Hybrid Tea with conical-shaped flowers, the buds of which are nasturtium red and apricot, these opening to more apricot and cream, with the red towards the outside. This gained a silver-gilt medal. The other variety, which secured a silver medal, was *Queen of the Musks*, a Hybrid Musk Rose of delicate shell rose pink colour. It is exceedingly free and a continuous bloomer, the trusses being very large.

THE ROCK AND WATER GARDEN.

THE BEST SAXIFRAGES AND HOW TO GROW THEM.

(Continued from page 468.)

The *Giant-leaved Megaseas* are at once the boldest and showiest of the entire race, and particularly valuable to the gardener by reason of their leaf-beauty and ornamental flowering. In the case of the finer evergreen kinds, as, e.g., *S. ligulata*, *S. l. speciosa* and *S. cordifolia purpurea*, the plants are not infrequently employed in spring bedding arrangements, where they constitute quite a feature. That last named, too, is of value at a later date, when the foliage assumes a rich reddish crimson hue, the stems, if allowed to remain, putting on a similar colour-tone. Those named, in conjunction with *S. cordifolia* (type) and *S. crassifolia*, are noteworthy also because of their perfect hardiness and their adaptability to town gardens and smoky districts.

As a great belt of 3 feet or 4 feet wide to a sumptuous planting of *Rhododendrons*, all growing

in the greatest luxuriance in soft, fat clay soil, I have seen them worthily playing their part in an arrangement noteworthy for its boldness, its liberal treatment and its artistic effect, in conjunction with the utmost simplicity and the truest zeal and economy. The idea was the grasp of the master mind; the very fitness of the partnership association was unassailable. Above all, it was good. It may be that we cannot all garden upon so liberal a scale as this, though the fact should not preclude our bringing together plants fitted for each other's company where permanent effect is the main object in view. On the boldest rock crest the plants have a beauty of their own, while for clothing many a sloping bank they are, perhaps, without an equal. Brilliant, Distinction, Progress, splendens and gigantea are some of the finer of a modern set, and all are characterised by pink, rose or reddish flowers on branching cymes from 1½ feet to 2 feet high. They ask for nothing more than ordinary garden culture, and may be increased quite easily by division, preferably during late summer and autumn, so that their spring flowering be not quite lost.

S. oppositifolia.—The "best" must of necessity include those which produce carpets of growth smothered with erect white, rose or crimson flowers quite near the ground from February to April. These are not happy near to towns or smoky districts, and prefer their native mountain home, where they produce sheets of colour, frequently in a veritable torrent. They are often seen in fullest splendour on quite barren rocks, or, anon, in cooler ground with more luxuriant growth and fewer flowers. In cultivation they love to get away from their pot prison, to ramble and flower galore in the cool sand of the plunging beds around, and the fact is worthy of note. Sandy peat of a fine character and loam in about equal parts suit them well, though they grow quite well and flower freely in most loamy soils. The varieties worthy of note are *alba*, *major*, *pyrenaica* and *splendens*, the last two very rich in colour. Next week I hope to conclude these notes by a selection of the choicest kinds suited to alpine-house or pot cultivation.
E. H. JENKINS.

THE GREENHOUSE.

SEASONABLE NOTES ON AURICULAS.

Watering.—It cannot be said with much truth that the Auricula demands a considerable amount of the cultivator's time during the autumn months, but the attention required is of the greatest importance, because neglect may easily spell the ruin of many valued plants. Watering calls for incessant consideration. It is well within the bounds of possibility that the soil in the pots will continue sufficiently moist for several days in the autumn; but, on the other hand, the soil will dry out rapidly in some pots, especially when the days are warm and sunny and the position of the frame is exposed. In the case of healthy offsets growing in small pots, water may be needed frequently for upwards of another month, and if a supply is not forthcoming when it is wanted, the chances are that the young plants will suffer seriously.

Rotting.—It is unfortunate that plants will show a tendency to rot off in the autumn and winter, and the efforts of the cultivator to prevent such an occurrence must be unceasing. When the drainage in the pots is defective, trouble from this cause is sure to arise sooner or later; and although it is

on the late side for disturbing the roots, it is wise to take the slight risk rather than run into one that is much greater and may lead to so many deaths. Preventives of rotting are open compost that is so porous that air is constantly passing through it, perfect provision for drainage and comparatively small pots, preferably those that are small in diameter compared with their depth. Another precaution which it will be sound practice to take is to keep the soil slightly on the dry side rather than on the wet side when the dull days come.

Autumn Trusses.—All Auricula-growers are agreed that trusses of flowers thrown up in the

remainder of the stem ought to be allowed gradually to wither away. There is an element of danger in cutting close to the crown of the plant; hence the advice to leave the whole length.

Green Fly.—There appears to be no plant grown in gardens which this pest will not attack at some time or another, and it is beyond dispute a nuisance to the Auricula-grower when it comes, as is often the case, in the autumn. The plants are extremely difficult to sponge properly, and it is commonly impossible to fumigate, so that these means of extermination may be regarded as out of court. The thing to do is to take a camel's hair brush and gently remove every fly that can be seen.

THE FLOWER GARDEN.

A LILY FOR THE OUTDOOR GARDEN AND GREENHOUSE.

LILIAM LONGIFLORUM yields to no other member of its genus in beauty and utility. Ever since its introduction to gardens about 1862 it has claimed the attention of cultivators, and to-day the traffic in this plant has attained to enormous proportions, in which the commercial enterprise of at least three continents is more or less at stake.

THE PERGOLA, WITH FLAGSTONE PATHWAY BORDERED WITH LILIAM LONGIFLORUM, AT COOMBE COURT GARDENS, KINGSTON HILL, SURREY.

autumn, especially on seedlings, are not to be desired, and various methods have been suggested to prevent this happening. It is, however, common for this to occur in the family, and it is doubtful whether any system of management will ever be devised that will reliably prevent it. Plants that are potted late in the season are almost as prone to throw up autumn blooms as those which are dealt with earlier; but, whatever the cause, it is a disadvantage to the grower, particularly so perhaps when seedlings are being dealt with. If we accept the inevitable, it causes little trouble, because the head should be immediately picked off below as soon as it is properly formed, and the

This task is rather a tedious one, but it is effectual, and when it is done with care one has the satisfaction of knowing that not a single enemy remains to play havoc with the plants.

Purchasing Plants.—The present is an admirable time to purchase young plants. It is surely unnecessary to urge readers of THE GARDEN to go to firms of the highest repute, such, for example, as those who offer their wares in the advertisement pages of this paper? If the youngsters are clean, healthy and vigorous when they arrive, it is not a matter of serious difficulty to maintain them in that condition; but weakly plants will cause endless worry.

F. R.

It is scarcely a matter for surprise that this species should appeal to a universal taste. The waxy white trumpets, with their rich fragrance, bright orange stamens and clammy stigma, are details readily apparent on close inspection, yet it is the graceful sweep of the erect stems, with the elegantly-poised flowers, that most directly force themselves on a casual observer, and it is this attribute that proclaims it a plant of inordinate beauty.

Its utility is disclosed by its adaptability to various methods of cultivation, which is further augmented by modified forms, some of which flower naturally in advance of the type, while

others flower later and so form a succession. *Lilium longiflorum*, the type, is a plant indigenous to China and Japan, where it is extensively cultivated, and whence it is largely imported to this and other countries, arriving here during autumn and winter. Besides the type, which is readily recognised in the dry bulb by its numerous small, close-set scales, there are several varieties. *Multiflorum* has broad, recurving leaves and averages more flowers to each stem. *Giganteum* is a taller plant, and ten days later in flowering than the type. *Eximium* is characterised by dark-coloured stems carrying flowers of stout substance, and is taller than *giganteum*. *L. Harrisii*, the Bermuda Easter Lily, so highly esteemed for early forcing, is but a geographical form of *longiflorum*, and is generally considered as being synonymous with the Japanese form, *eximium*. Unfortunately, the source whence *L. Harrisii* usually emanates has become unreliable, and bulbs grown in Formosa are coming much into favour for early forcing. The variety *formosanum* takes its name from this Eastern island, and it appears to approximate to the Japanese variety *multiflorum*. Bulbs come to hand in this country during September and October, and if potted up before the end of November there is little difficulty in flowering it by Easter. It is a superb Lily, bearing immense flowers on very stout stems that frequently attain a height of 4½ feet.

L. longiflorum and its varieties, when grown in pots, are most desirable plants for furnishing greenhouses and conservatories. Single bulbs may be placed in 4½-inch pots, or several bulbs placed in larger sizes. The soil should consist of good fibrous loam, three parts; leaf-soil, one part; spent Mushroom-bed manure, one part, with a small quantity of sand added. The bulbs are placed an inch beneath the surface of the soil and potted firmly. No top-dressing is necessary, except in the case of *formosanum*, the bulbs of which should be kept 1½ inches to 2 inches beneath the surface when potting. After potting place in a cool structure with plenty of light, it being advisable to encourage stout, firm growths and free rooting in the early stages, without which no good results can follow. After-treatment depends upon the season in which the plants are required to bloom. Early-potted bulbs of *formosanum*, when well rooted, require a temperature of 50° to 55° in order to flower them by the end of March and early April. A similar temperature will induce *longiflorum* and its variety *multiflorum* to flower during May, while grown under cool greenhouse treatment these latter flower during early June. The varieties of *giganteum* and *eximium* flower ten to fourteen days later.

In the open garden *L. longiflorum* and its varieties introduce a distinct type of beauty, which can only be equalled by another member of this genus,

namely, *L. candidum*; but, unfortunately, this species is impossible in many gardens owing to ravages by the Lily disease, so that under these circumstances *L. longiflorum* is a most welcome substitute, and one that can be recommended with all confidence. It lends itself to decorative effect in most positions where hardy flowers are grown, such as in beds and borders, and, as shown in the illustration on page 477, it is peculiarly effective when occupying the parallel borders of a pergola. The combination of colour derived from the overhead Roses and Clematis becomes sharply contrasted with the snowy purity of the Lilies, while the richness of the former in conjunction with the

THE NEW EARLY-FLOWERING COSMOS WHITE QUEEN. A BEAUTIFUL FLOWER FOR AUTUMN BORDERS.

stateliness of the last-named produce an effect that is altogether pleasing, and, incidentally, results in freeing formalism in garden design from all charge of harshness.

When grown in the open garden, I am a strong advocate of planting *longiflorum* and its varieties in the dry state. For this purpose the ground should be carefully prepared in autumn, the position being well drained and the ground trenched to a depth of 2 feet. The best soil is a medium loam, to which may be added, during trenching, a quantity of thoroughly-decayed leaf-soil and spent Mushroom-bed manure. Bulbs should be procured towards

the end of October or early in November and planted during the latter month. Plant the bulbs 12 inches apart, allowing 4 inches of soil to cover them, and surround each bulb with sharp sand. On heavy soils and in districts subject to much wet in winter, it is advisable to cover the ground after planting with some protective material, such as Bracken or straw.

Provided good bulbs are obtained in the first instance, at least three years', and most probably four years' good service will be rendered by them, as it is only under most favourable conditions that *L. longiflorum* maintains its flowering strength longer. After-treatment consists chiefly in encour-

aging the maximum vigour in stem and leaf. To this end copious waterings should be given during the growing season, using rain-water, alternated with liquid manure made from farmyard manure in a thoroughly-decomposed condition. Water containing lime or iron in quantity should never be applied to this Lily under any circumstances.

THOMAS SMITH.

Coombe Court Gardens, Kingston.

A NEW WHITE COSMOS.

On this page we publish an illustration of a new *Cosmos* named *White Queen*. It is a graceful and elegant variety, quite pure in tone. As a border flower for summer effect it will doubtless prove an acquisition. It is quite as free-flowering as *Cosmos bipinnatus*, and commences blooming much earlier. In the cultivation of *Cosmos* it is well to note that they flower with the greatest freedom when grown on rather poor soil. On ground that has been heavily manured and copiously supplied with water, the plants are much inclined to produce an over-abundance of their fine feathery foliage at the expense of flowers.

FLOWER-BORDERED ROADS AT PURLEY, SURREY.

THERE are few towns in the country that can boast of such flower-bordered roads as Purley in Surrey, where William Webb, Esq., the owner of the Upper Woodcote Estate, has formed two "floral" roads on his estate. One is known as Silver Lane, and is composed of avenues of that most

graceful of native trees, the Silver Birch, carpeted with spring flowers and thousands of spring-flowering bulbs, starting with Winter Aconites and Snowdrops; then come patches of all the Croci, white, blue, and yellow; followed by Anemones until March brings us to the Daffodil. Thousands of these have been planted in scores of varieties—the lordly trumpet and the humbler Lenten Lily, the Poet's Narcissi and all its kindred are to be found, not planted in dozens, but in long stretches, as they should be. The Tulip, too, is represented, and its splashes of colour add beauty here and there. A bulb catalogue would almost

have to be reproduced if all the names were given in detail. Enough has been said to prove that in the early months of the year Silver Lane is very beautiful with its flowers, and at other seasons of the year the Silver Birch makes a delightful road. I am sorry I cannot send you a photograph of it, but I have made arrangements to have one taken this coming spring.

The other road deserves rather fuller description; it is known, I believe, as the South Border, and is composed very largely of herbaceous plants, with patches here and there of annuals. Nearly all have been raised from seed by Mr. Webb's able foreman, Mr. D. Bignell, but many of the newer varieties of herbaceous plants have had, of course, to be purchased, and no expense has been spared to get the best and the best only. A glance at the list of, say, Phloxes, will show the truth of this statement. The border was planted last autumn, and in this instance the flowers are only on one side of the road, *i.e.*, the north, as it was felt that it would be useless to attempt to make a satisfactory display of herbaceous plants with a northern aspect. The flower-bed is 12 feet wide and about four feet deep. It was made of top spit, with plenty of manure. In front of it is a 5-foot grass path, then a ha-ha, *viz.*, a 3-foot ditch with a sunk wall, and a low wire fence to protect the flowers from the public.

At the back of the border is a strong Privet hedge as a background and shelter from the cold winds; and, in order to prevent the roots of the Privet robbing the plants, a slate wall has been sunk to separate the two. The main scheme is herbaceous plants; but to prevent monotony in so long a border (nearly one-third of a mile) the line is broken here and there by weeping Roses, Clematises of sorts, Sweet Peas and similar plants. The whole of the planting was carried out by Mr. D. Bignell, who is still responsible for the upkeep.

The following are a few of the immense variety of plants the border contains: *Anchusa italica* Dropmore variety has been good; *Anemone Queen Charlotte*, just now at its best; *A. japonica alba*, *Artemisia lactiflora*, *Bocconia cordata*, *Chrysanthemum King Edward VII.*, flowers good; *Coreopsis grandiflora*, *Delphiniums Queen Wilhelmina* and the King of *Delphiniums* have been greatly admired for their beautiful spikes of bloom; *Echinops Ritro*, *Erigeron speciosus grandiflora*, *Eryngium oliverianum*, fully 4 feet in height and beautiful heads of bloom, now a deep blue in colour; *Helenium pumilum magnificum* is just now one mass of good bloom; *Helenium Riverton Beauty* and *Riverton Gem* are also coming into flower, fully 5 feet in height; *Solidago Golden Wings*, some fine spikes; *S. Buckleyii*, also some fine plants; *Phloxes Elizabeth Campbell*, *Frau Antonin Buchner*, *Flora Hornung*, *Etna* and *Le Soleil* have all made a fine show, the weather having suited them; *Le Madhi*, too, has had splendid heads of bloom; *Statice latifolia*, *Scabiosa caucasica*, *Gaillardia*, *Gypsophila paniculata*, in groups; *Verbascums Caledonia* and *A. M. Burnie*; *Hollyhocks*, in large variety, some are fully 12 feet in height, and have been excellent; *Onopordon bracteatum*, the large Thistle, has made some fine specimen plants fully 8 feet in height; some fine groups of *Pentstemons*, *Scabious*, *Helichrysum*, *Asters*, *Stocks*, *Antirrhinum*, annual *Chrysanthemum*, *Salpiglossis* and *Larkspurs* (rosy scarlet) are just now in full flower; *Lilium auratum*, *L. Henryii*, *L. tigrinum* and *L. speciosum rubrum magnificum* are all showing promise; *Dahlias* in numerous varieties, *Cactus*,

Pompon and decorative, and these with *Chrysanthemums* and *Michaelmas Daisies* carry the flowering season right on to the late autumn. Spring-flowering bulbs are also freely introduced, so that at no season of the year is the South Border without interest.

The newly-finished lodge at the entrance, known as *Watersmeet*, represents a cottage on the hillside, with streams of water converging to a *Lily pond* below.

Such is a brief description of an attempt to get away from a normal building estate; and if Mr. Webb's example could only be followed, as it might easily be, by landowners throughout the country, surely this England of ours would be a better and a brighter place to live in. The influence of flowers is manifold, and it is all for good. Purley is to be congratulated that that part of it belonging to William Webb, Esq., at any rate, is being developed on such lines. Another road, which is

"Will my soil grow Apples?" is the first question, and the reply can always be "Yes." On the lightest sands, heaviest clays and poorest chalk soils Apples can be found thriving, *provided always* due care has been given in selection, and also to make up soil deficiencies. The use of the surface-rooting *Paradise* stocks enables the roots to be kept in the best soil, and, still more important, where the manure applied can reach the roots, I should like to say more here on the subject of manure for fruit trees, but perhaps a later article may give an opportunity.

The Best Type of Tree.—The next consideration is the form of the tree. I am always strongly inclined to forms which are the least removed from the natural. Horizontal espaliers must be recognised as partly ornamental, and what is gained in this direction is lost in others. For crop and ease of culture there is nothing better than the open bush. A slight concession to decorative effect

A PORTION OF THE HERBACEOUS BORDER BESIDE A PUBLIC ROAD AT PURLEY, SURREY.

bordered with *Roses*, I hope to describe in a subsequent issue. HERBERT E. MOLYNEUX.

THE FRUIT GARDEN.

THE BEST APPLES AND HOW TO GROW THEM.

IT has often occurred to me that if the culture of Apples were more difficult, we should see better fruit grown in our gardens. The obliging nature of the Apple, which, cultivate we never so unwisely, still produces some sort of crop, has prevented it from having the careful treatment it deserved. We all know the row of pyramids or espaliers down the middle path of the kitchen garden, shaded on one side by tall herbaceous plants and crowded on the other by the encroaching Cauliflower. It is on behalf of these often ill-treated trees that I take up my pen.

admits the pyramid, and where space is no consideration, the half or full standard give those whose need is quantity, but not immediate return or large individual fruits, their desires in the easiest way.

How to Plant.—Given, then, the tree, how, when and where shall we plant it? Granting good garden soil which has not been previously occupied by fruit trees, plant the trees in it as it is. Trees on *Paradise* stock with their shallow roots will not require a large hole, but the deeper-rooting and tap-rooted *Crab* stock which is used for standards and half-standards will want more accommodation. Plant firmly (this would be in double capitals if the Editor permitted!) and stake all large trees which are liable to be blown about. The very vexed and thorny question of pruning after planting is one that I hesitate to touch; but, taking my courage in both hands, I say, "Prune at once if under three years old; if over, wait till the following winter," and pass rapidly on to the question of "when" to plant.

When to Plant.—In good, well-drained soils, late October to November are good, but by no means the only months. Any time during the winter, if the weather is open and the soil not waterlogged, it is possible to safely transplant trees, and in my own case all moving is done in March, with results entirely satisfactory. In wet soils, or in high altitudes where winds are cold and drying, the later planting is infinitely preferable.

Where to Plant.—The third question of "where" is in most gardens limited to a small area. It should be an endeavour to plant always on the highest land, where frost in spring is less felt, where the trees will have a free air circulation and, growing "hard," will resist aphid and other pests. Avoid the proximity of large trees, even when they do not actually shade your fruit trees, as the air near them is often stagnant and causes a sappy growth, which is a temptation to aphid such as they are unable to resist.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Cattleya Memoria H. A. Tracy.—A magnificent hybrid *Cattleya* of exceptional size and perfect form. Shown by H. S. Goodson, Esq., Putney, S.W.

Dendrobium Shutei.—An interesting new species from the Philippines with pure white flowers. Shown by Messrs. Sander and Sons.

AWARDS OF MERIT.

Odontioda devossiana Fowler's variety.—A showy dark red hybrid. Exhibited by J. Gurney Fowler, Esq.

Lælio-Cattleya St. Gothard Glebe Variety.—A shapely-flowered hybrid resembling its parent, *Cattleya hardyana*. Shown by C. J. Phillips, Esq.

Chrysanthemum Crimson Polly.—This, as its name partly suggests, is a crimson sport from the well-known early-flowering golden yellow variety

individual flowers are very large and of rich pink colour, the panicles free and open, and giving evidence of that good attribute in a herbaceous Phlox, viz., the production of a large number of lateral shoots. The habit is most vigorous. From Mr. J. Box, Lindfield, Sussex.

Pentstemon Gaddesden Gem.—This is not one of the Gem class proper, and of which Newbury Gem is the type, but belongs to the large-flowered or florists' class, and is one of the finest we have seen. The flowers are crimson-coloured and have a white throat. A bed of it should look very telling. From Mr. A. G. Gentle, Little Gaddesden.

Dahlia Queen Mary.—A rose pink flowered variety of the large decorative set, with good strong stem. It is very showy. From Messrs. Cannell and Sons, Swanley.

Dahlia Crawley Star.—The first of a new type to which the name *Cosmea*-flowered has been given, and which is at least suggestive of the elegant character of a beautiful variety. The colour is rosy pink, and there are two rows of petals having a slight ring of crimson at the base. From Messrs. J. Cheal and Sons, Crawley.

Dahlia Selma (Pompon).—This in its set is quite a model flower, the florets perfectly and regularly arranged. The colour is palest fawn, with a tendency also to pale orange. From Mr. Charles Turner, Slough.

Dahlia Papa Charmet (Decorative).—A magnificent maroon crimson flowered variety of the large decorative set, with fittingly bold and strong stems. It is very handsome-looking. From Messrs. Hobbies, Dereham, Norfolk.

Dahlia Ideal (Collarette).—The outer florets are maroon crimson, the smaller inner florets of a yellow tone. The contrast is good.

Dahlia Albert Maumene (Collarette).—The outer florets are of rosy cerise colour, with white central florets. These were exhibited by Mr. J. B. Riding, Chingford.

Dahlia Jack Riding (Cactus).—The incurving florets are crimson, shading to orange at the base. A large and handsome variety.

Dahlia Nantwich (Cactus).—A fine incurving flower of the exhibition type, light fawn.

Dahlia Dolly (Cactus).—Crimson scarlet, heavily tipped with creamy white. These three came from Messrs. James Stredwick and Sons, St. Leonards.

The foregoing Dahlias, having been adjudicated upon by a joint committee of the Royal Horticultural Society and the National Dahlia Society, are entitled to the award of merit of the former and the first-class certificate of the latter.

Potato The Diamond.—A heavy cropper with oval, smooth-skinned tubers. Shown by Messrs. Barr and Sons.

Strawberry Merville de France.—An autumn-fruiting variety producing heavy crops of highly flavoured fruits. Shown by Messrs. George Bunyard and Co., Limited.

All the foregoing were shown before the Royal Horticultural Society on the 10th inst., when the awards were made.

A PORTION OF THE BORDER, PHOTOGRAPHED RECENTLY, A PLAN OF WHICH IS GIVEN ON THE OPPOSITE PAGE.

Pruning.—There are two general counsels which seem to be more needed than others, and they are these: "Thin your branches" and "Thin your spurs." The main branches of a standard bush or pyramid tree should be so placed that King Charles would have found them quite useless for the purpose that he sought the Oak at Bosobel. The thinning of spurs is perhaps the most neglected of all pruning operations. The exercise of imagination will aid here as elsewhere. Imagine on each spur one fruit of such a size as would ensure the first prize label being placed on it at next year's show. This will give you at once a measure of the necessary thinning. But it may be said, "We must have some as insurance against those which fail." As, however, each bud contains five flowers, these will still be enough for that purpose.

Maidstone.

E. A. BUNYARD.

(To be continued.)

Polly, and is therefore possessed of all the good attributes of that sturdy-growing and excellent sort. The plant is about two feet high, the colour a rich crimson. From Messrs. William Wells, Limited, Merstham.

Helenium autumnale rubrum.—A large and reddish crimson flowered variety of a well-known plant, which, if constant, should prove a great gain. The plant is of a tall habit of growth and a most profuse bloomer.

Achillea Ptarmica Perry's White.—A much larger and later flowering variety than either Bouquet or The Pearl, and, like these, belongs to the above-named species. The new-comer should prove of much usefulness to the gardener and the florist-decorator. These two plants came from Mr. Amos Perry, Enfield.

Phlox Rijnstroom.—This may briefly be described as a much-improved Pantheon. The

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Spring Bedding Plants. such as *Myosotis*, *Wallflowers*, *Polyanthus*, *Alyssum*, *Arabis* and *Aubrietias*, that are growing in lines should be given every encouragement by frequently stirring the surface soil between the plants whenever the weather permits, so that they will form good, healthy plants for placing out in their permanent quarters next month.

Pentstemons.—In order to perpetuate the better varieties of these, and also to ensure early-blooming plants next year, cuttings should be taken now and inserted in sandy soil in well-drained pots, preferably 5-inch, or else in a close cold frame containing a similar mixture. Where growths are plentiful, I prefer using the tips only; but if a quantity of a variety is desired, the growths may be cut up into lengths, *i.e.*, several cuttings made of one shoot. Make the soil firm and see that the base of the cutting reaches the bottom of the hole. Well water in and keep close. Shade from bright sunshine, and damp over lightly early in the day when inclined to be bright. As soon as rooted admit more air.

Antirrhinums.—Any special varieties may be propagated in much the same manner as the above.

The Rock Garden.

Sedum spectabile atropurpureum.—For this season of the year this bold and handsome species is a decided acquisition, valuable alike for the front of the herbaceous border, growing fully a foot in height, and each growth surmounted with a flat head of showy rosy crimson flowers.

Hardy Cacti.—Though departing from the usual class of plants, the hardier of the Cacti form an interesting class of plants for associating with rock or stone, and are particularly effective with the red sandstones. A position facing south or south-west should be chosen for them where they will receive full exposure to the sun, and a corner backed with fairly high walls will be another great advantage. Through the winter months some protection ought to be afforded them from heavy rains and other inclement weather, or the plants should be removed to a cool house. In such a position *Gerberas* also flower freely, as do the *Mesembryanthemums*, both of which should be potted and wintered in a cool house.

Plants Under Glass.

Violets.—The culture of Violets for supplying blooms during the winter months is practised in almost every garden, large or small, in some attended with a greater measure of success than others, due, I think, to the conditions suiting their requirements, though there are many little details to observe, and I will mention a few of the salient points necessary to ensure success. The frames should occupy an open position on fairly high ground, if possible, and whether they are heated or no matters but little. Avoid too great a depth of soil. A foot will be ample; less will suffice.

Lachenalias.—These are beginning to grow, and should be repotted or placed in baskets without delay and grown on in a cool house. When treated in the latter manner, they are most effective and quite easy to manage. Line the basket with moss, place a little soil in the bottom, and plant the bulbs upside down about four inches apart; then add a little more soil and so work the bulbs round the sides of the basket. Give a good soaking and hang up the basket.

Fruits Under Glass.

Earliest Trees of Peaches and Nectarines.—Young trees are often benefited by being lifted and the roots brought nearer to the surface. With trees that are going to be forced early, any such work should be put in hand at once before the foliage falls, as then the trees will have time to recover from the treatment. Syringing and shading should be done if the weather is bright and warm, but give abundance of air. For these and all other stone fruits add a liberal supply of old mortar rubbish and a sprinkling of wood-ashes, but avoid the use of manure, which generally only tends to make rank growth.

Trees and Shrubs.

Flowering Crabs.—During the month of August and well into September these, when in fruit,

are extremely beautiful and admirably adapted for planting not only in shrubberies, but also as specimens on the lawn, in the wild garden and more open positions in the woodland, and, apart from their freedom of flowering in the spring and highly-coloured fruits in the autumn, are highly esteemed for making that excellent preserve, Crab Apple jelly. A few of the best among the varieties we grow are John Downie, Beauty of Montreal, Dartmouth Crab, *Pyrus prunifolia fructu luteo*, *P. niedwetzkyana* and *P. baccata fastigiata bifera*.

Work Among Shrubs.—As soon as convenient it is a splendid idea to go through and mark any shrubs that need removing when the time comes, so that growth will not be too congested next year. See that the climbers are safe against wind and tie in any straggling growths, at the same time cutting out any useless old wood.

The Kitchen Garden.

Lettuce.—Another sowing should be made in a cold frame for producing supplies in the winter, the earlier sowings thinned and transplanted into a sheltered warm position or into skeleton frames. Bath Cos, Hicks' Hardy White and Hammersmith are good varieties.

Tomatoes.—The continuance of this crop will greatly depend on the weather. The results up to date have not been very satisfactory. Thin out the foliage and stop the plants, so that plenty of air and sun can reach them. As soon as the crop is threatened with frost, pick the largest fruits and place them in a dry, sunny position to ripen.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Dahlias.—Many of the Cactus varieties make only a slight display unless a good deal of the growth is removed so that the flowers are shown. The newer kinds of decorative Dahlias have long stems, but some of the blooms are so heavy that it is essential to tie them back. Single varieties must have the bloomed-out stems removed, else the seeds they bear stop the plants from flowering. The smaller-flowered decorative sorts, as well as the others, should be examined twice a week and dead blooms removed.

Larkspurs.—It is a mistake to be too particular to cut out the flower-stems which apparently have done flowering. If grown strongly and the plants are in perfect health, little flowering shoots are pushed from the sides and keep the plants gay for a very long time. See that the ties are perfect, else autumnal storms may break down the plants, which this year are more than usually tall and robust.

Montbretias.—These are not only very late, but hundreds have failed to flower at all, probably a result of being too dry last year. It may be worth while even yet to pull out the weakly growths from among the more robust, so that these may be the better enabled to become as perfect as possible before a cessation of activity.

Nepeta Mussini.—Short pieces dibbled thickly into a shallow bed of soil in a cold frame kept close till the turn of the year will all root and become nice stocky material for planting out in mixed borders or for carpeting Rose-beds and other purposes. It is indubitably one of the nicest free-flowering plants of a lavender colour that are available, and well worthy of more extended cultivation in gardens where soft colouring is essential.

Chrysanthemums.—The autumn-flowering varieties will now be in bloom, and are of much value to lift and mass where other plants have failed or, what is as bad, have become shabby. Always transplant in the afternoon, always plant deeply, always water profusely and always stake securely, and they will give satisfaction. I like the tall-growing varieties in preference to low-growing sorts, buff, bronze, yellow and crimson being the colours preferred.

The Rock Garden.

Saxifraga Andrewsii.—This is one of the nicest of late-flowering plants. It does not thrive in a dry soil; therefore a damp position should be chosen for it, and, if the soil inclines to be heavy, it will succeed all the better.

Propagation.—Cuttings of quite a large number of semi-shrubby plants will root if taken now and dibbled into a soil-bed in a cold frame or under hand-glasses or cloches. Some things can be kept only by means of constant propagation. Such are some of the New Zealand Veronicas, which one is never sure of standing over winters. The many varieties and species of shrubby Candy tufts also root freely if taken now. Alpine Phloxes and Dianthi of the plumarius section are others. None of these asks for much space, and may safely be inserted almost touching each other, but leaving 3 inches between the rows.

Alterations.—No time of the year is more suitable than this for making alterations, either on the rockery as it exists or extending it in any direction, there being yet time to replant and get plants re-established before the rigours of the winter season are upon us. Everything being prepared, an enormous amount of work can be overtaken in a week or ten days.

The Plant-Houses.

Rhododendrons.—These may be returned to greenhouses at any time, first cleaning them thoroughly, seeing that the drainage is in perfect condition, the pots washed clean and the surface of the soil refreshed. There is usually much dead foliage on Azaleas, which should be shaken off and the plants syringed, laying the upper edge of the pot during the operation on two bricks to save the soil from being wetted. Camellias may either be syringed with an insecticide or sponged.

Chrysanthemums.—Forward plants will be much better placed under cover in a cool structure than left to the mercy of the elements. The earlier of the bush plants, both double and single, will need to have the buds thinned, and the plants will probably be much benefited by an application of loam and manure in equal proportions, with a small proportion of an approved artificial manure to the surface, and at least half an inch in thickness. Mildew must be looked for and counteracted by dustings of flowers of sulphur.

The Vegetable Garden.

Tomatoes.—Late Tomatoes are much later than usual, owing to the inclement weather throughout. To ripen them off they must now be treated to artificial heat and the minimum of water at the root. The Tomato seems capable of thriving without water, and at this period it is astonishing how long the plants go on without receiving any. Every lateral or axillary growth as it pushes should be rubbed off, and no foliage retained other than the few main leaves. It is unnecessary to ventilate the structure in which the plants are growing.

French Beans.—These cannot be expected to bear much longer, the first autumnal frost usually terminating their existence. Meanwhile see that no pods are left to mature, and the soil between the rows may be loosened with a fork, which will be a help to the crops as long as the weather continues fine. Those in frames should be well forward, and if too robust, which sometimes happens, the more weakly growths should be removed. It is usual in big establishments to commence forcing in pots at this season, fresh batches being prepared at short intervals throughout the season.

The Fruit Garden.

Apples.—Continue to pick the more forward fruits of soft-fleshed varieties and store them in the Apple-room. They keep perfectly if heaped on the shelves, provided the fruits are sufficiently matured and no damaged ones are among them. Keep the windows open meanwhile. Fruits left on the trees will plump up considerably.

Pears.—Quite a number of varieties will need attention, looking them over about twice every week for the next three weeks or so. The fruits must be laid out singly in one layer, and should be in a dry room apart from Apples if it can be so arranged. By picking at intervals, the period of use of each variety is extended. An interval when none ripens naturally may be bridged by introducing the more forward fruits into a vinery or other heated structure.

Brambles.—The Parsley-leaved variety is of much value now and later, and carries immense crops. We also grow a quantity of Japanese Wineberries, which are valued for mixing with Apples in tarts. Birds are very fond of this fruit, and where they abound it is almost imperative to place doubled nets over the bushes.

R. P. BROTHERTON.

Tynningham, Prestonkirk, N.B.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEA SEEDS (A. B.).—The pods of Sweet Peas should be left on the plants until they are quite dry. They feel greasy to the touch before that stage is reached. If they are stored in a dry place the seeds can be removed from the pods at convenience.

SWEET PEAS (Perplexed).—Most of the yellowing of Sweet Peas is due to some root trouble, as one might suspect from the appearance of the plants; but unless the whole plant, and especially the root, is sent, it is quite impossible to be sure what the cause of the trouble is.

SWEET PEAS DISEASED (Dolphin).—There is nothing you can do that will benefit the Sweet Peas. Secure what flowers you can from them and then burn the lot, roots and top growth. It is unwise to grow Sweet Peas on the same ground two years in succession.

FRAGRANCE IN SWEET PEAS (W. B. B.).—Practically all the old varieties, such, for example, as Lady Griseld Hamilton and Dorothy Eckford, are very sweet, and would answer your purpose. You will be particularly interested in the Rev. Joseph Jacob's note on the subject on page 378 of THE GARDEN dated July 27. The foods which you name should give you excellent colour, but you might try nitrate of potash now and again at half an ounce to the gallon of water, giving three gallons to the square yard.

CALOCEPHALUS (LEUCOPHYTA) BROWNII (Regular Reader).—This silver-leaved bedding plant is a native of Australia, and during the winter requires the protection of a greenhouse. It is propagated by cuttings of the young growing shoots, taken off at a length of about two inches, and dibbled into a compost made up of equal parts of loam, leaf-mould or peat and silver sand, the whole being passed through a sieve with a quarter of an inch mesh. The pots prepared for the reception of the cuttings should be quite clean and effectually drained. A little of the rougher compost which does not pass through the sieve may be placed immediately over the crocks, and on this the finer soil, made quite level and pressed down moderately firm. The cuttings must then be dibbled in securely, care being taken to avoid overcrowding, while, at the same time, space need not be wasted. When a pot is finished, it should be given a good watering through a fine rose in order to settle the soil thoroughly in its place. Then the pots of cuttings must be placed in a close propagating-case, or covered with a bell-glass in a greenhouse temperature. They must, of course, be watered when necessary, have any signs of decay removed and be kept shaded. When rooted they may be potted singly into small pots, using much the same compost but with a lesser amount of sand, and kept in the greenhouse or in a frame till the bedding-out season arrives. Plants of the Calocephalus can be purchased at a cheap rate from those who make a speciality of summer bedding plants.

TREES AND SHRUBS.

FABIANA IMBRICATA (A. G.).—It is quite usual for the points of the branches of Fabiana imbricata to die after flowering; in fact, it is a good plan to remove the tops of the shoots as soon as the flowers are over. Providing your plant is otherwise healthy, there is no reason for any unhealthiness about it, and as you say that new shoots are being formed, we presume that it is in quite good condition.

HONEYSUCKLE GOING WRONG (A. W.).—It is possible that your Honeysuckle is infested with aphids, and if this is the case you cannot do better than syringe it well with a nicotine solution or with a solution of soft soap and Quassa chips. There is no necessity to peel the bark off the stems, neither do you need to cut the plant back hard, as you suggest. It would, however, do the bush good to thin it well and cut the remaining branches back a little. The thinning may be done at once, and the other pruning in February next.

TRANSPLANTING EVERGREENS (F. T. H.).—Providing the weather is damp, you may transplant Camellias, Hollies and Magnolias towards the end of August; but Laurels would be better left until the middle of September. In the case of very dry weather occurring, leave all until there is rain. After transplanting, shade any particular plants with canvas during bright weather for two or three

weeks and syringe the branches twice daily. It is also a good plan to reduce the branch system a little on large plants, particularly if the roots have been much disturbed. Whenever possible, however, a ball of soil should be removed about the roots of each plant.

LEYCESTERIA FORMOSA (Ilex).—Leycesteria formosa may be grown in a variety of ways. Some people prefer to see it as a naturally-grown bush. In such cases little or no pruning is required unless the bushes become very dense and the inner branches die. The necessary pruning should then be the removal of the worn-out wood. Other people prefer to cut away a certain amount of old wood each spring. This is a very good method, for it leaves the plant rather thin, and finer shoots and inflorescences are the result. Another method of culture is to cut the branches to the ground-line in March each year and rely on annual growths. Such shoots are effective in winter by reason of their bright green bark. On no account prune as soon as the flowers fade, for a further period of beauty may be looked forward to when the showy fruits are ripe.

KITCHEN GARDEN.

WART DISEASE ON POTATOES (W. H. S.).—The Potatoes are badly attacked by the disease called warty disease, due to Synchytrium endobioticum. You must at once notify the disease to the Board of Agriculture, Whitehall Place, London, S.W., and their inspector will give you further instructions.

CELERY (Reader).—Your Celery, so far as we can see from the poor and very badly-packed specimens sent, is attacked by aphids. Spray with paraffin emulsion or with Quassa and soft soap. Plants should always be packed in soft paper and placed in boxes, else they arrive in a very mangled state.

CELERY ROTTING (Shropshire).—The rotting of the Celery appears to have been caused by the bacteria, which apparently made their way into the plants by wounds made by some insect attack near their base. The specimens sent show the wounds quite plainly.

INJURY TO PEAS (J. C.).—The roots of the Peas are attacked by fungi. You are probably right in thinking the recent wet weather has contributed to the trouble, which has been prevalent both last year and this. It is frequently the case, too, that heavy manuring assists the fungus rather than the Pea. Thorough drainage and soil in good heart, but not with manure in layers, are the great things to aim at.

MISCELLANEOUS.

NAME OF POTATO.—H. Weller.—We think the Potato is Asleaf Kidney, but it is impossible to say definitely without flowers and foliage.

NAMES OF PLANTS.—R. S. G.—We think the Pelargonium is Kingswood. The Rose is usually shy in blooming, and we do not think you can do more than you have done.—*F. G. K. Herts.*—1, Silene fruticulosa; 2, Cardamine triflora; 3, Acaena sanguisorba; 4, Sedum spectabile; 5, send in flower.—*Kentish.*—1, Pinus insignis; 2, Pinus excelsa.—*T. P. Alvechurch.*—Eucumis punctata, will grow in cool house or sheltered corner outside.—*H. J. W., Tavistock.*—1, Achillea Ptarmica flore pleno; 2, Helianthus giganteus; 3, Sedum Telephium; 4, Fuchsia thymifolia; 5, Lobelia laxiflora; 6, Spiraea Menziesii; 7, Spiraea canescens; 8, Mimulus cardinalis.—*E. H. B., Esher.*—Senecio tangentius, a Chinese plant, not a native of these Isles.—*J. T., Wareham.*—Cupressus pisifera plumosa argentea.—*E. H., Aldrie.*—1, Funkia ovata; 2, Echinops exaltatus; 3, Solidago lanceolata (Golden Rod); 4, Aster corymbosus; 5 and 6, too scrappy to identify; 7, Caltha palustris (Marsh Marigold); 8, Rudbeckia laciniata; 9, Polemonium caeruleum (Jacob's Ladder).—*G. K. M.*—1, Probably Amorpha canescens; 2, Danæ Laurus (Alexandrian Laurel); 3, Anaphalis margaritacea (Pearly Everlasting).

NAMES OF FRUITS.—R. Childs.—1 and 2, Souvenir du Congrès; 3, Easter Burre; 4, Benrè Diel; 5, Yorkshire Greening.—*W. D. C.*—7, Hollandbury; 31, Worsley Pippin; 32, Lord Grosvenor; 21, Crimson Queen; 8, Cox's Pomona; 9, Old Nonsuch; 5 and 26, King of the Pippins; 24, Wellington; 29, Hawthornden; 23, Allen's Everlasting; 2, Worcester Pearmain; 30, Leathercoat Russet; 27, Ribston Pippin; 10, Boston Russet; 28, Cellini Pippin; 11, Verulam; 15 and 17, Williams' Bon Chrétien; 25, Belle Julie; 14, Fertility; 13, Beurré Hardy; 12, Doyenné du Comice; 20, Beurré de Aremberg; 4, Lawson's Golden Gage.—*Mercury.*—Apples: 1 and 11, Ribston Pippin; 2, Lane's Prince Albert; 3, Yorkshire Greening; 4, Worcester Pearmain; 5, Lord Grosvenor; 6, Yorkshire Beauty; 7, Stamford Pippin; 8, 12 and 15, Cox's Orange Pippin; 10, Mère du Ménage; 13, Ecklinville Seedling; 14, Stoke Pippin; 16, Pickering's Seedling; 17, Reimette du Canada; 18, Bowhill Pippin; 19, Hambleton deux ans; 20, Warner's King. Pears: Beurré d'Amanlis; 2, Beurré de Jonghe; 3, Josephine de Malines; 4, Doyenné du Comice; 5 and 13, Catillac; 6, Beurré Clairgaze; 7, Duchesse d'Angoulême; 8, Souvenir du Congrès; 9, Uvedale's St. German; 10, Gansel's Bergamot; 11, Winter Nellis; 12 and 17, Williams' Bon Chrétien; 14, Fertility; 15, Brown Burre; 16, Marie Louise; 18, not recognised; 19, Marie Guise.—*R. M.*—1, Cornish Gillyflower; 2, Golden Noble.—*W. B.*—7, Pearson's Plate; 51, Yellow Ingestre; 58, Old Nonpareil; 66, Cox's Orange Pippin; 48, Cox's Pomona; 37, Doyenné du Comice.—*J. T., Wareham.*—Figs: 1, 2 and 4, Brunswick; 3 and 5, Brown Turkey; see also "Names of Plants."—*G. Tyler.*—1, Pittaston Duchess; 2, Beurré d'Anjou; 3, Green Pear of Yar; 4, Doyenné du Comice; 5, Hoary Morning; Shepherd's Bullace.

SOCIETIES.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THIS, the leading Scottish society, held its annual autumn show in the Waverley Market, Edinburgh, on September 11 and 12. It was anticipated that the exhibition would hardly be up to its usual high level on account of the nature of the season, and also to the fact that the special efforts made in connection with the Glasgow and Dundee shows would prevent some exhibitors from competing. To a certain extent the latter circumstance affected the exhibits, but others were sent, and the show, as a whole, was superior to the average.

COMPETITIVE CLASSES.

In the competitive section the chief class was that for the Scottish Challenge Trophy for Grapes, the prize consisting of the 50-guinea challenge cup, presented by Mr. W. H. Massie, a gold badge and £6 in money. As Mr. James Dixon, gardener to Lord Rowallan, Rowallan, Ayrshire, had won the cup twice previously, keen interest was felt regarding the winner this time. Mr. Dixon again proved the victor, and the handsome cup now becomes his property. This year he again met strong competition, but won by only two points over Mr. J. H. Goodacre, Elvaston Castle. Out of a possible 74 points Mr. Dixon obtained 57½, his best being two bunches of Madresfield Court, on each of which he only lost 1 point; Mr. Goodacre obtained 55½ out of 74; third, Mr. D. Halliday with 53 out of 74; fourth, Mr. G. Mollison with 42½ out of 74.

Another class of much interest was that for a table of dessert fruit decorated with plants. Here Mr. Goodacre was first for both fruit and decoration, gaining 100½ points for the former and 14 for the latter; second, Mr. W. Galloway, Gosford, with 92½ for fruit and 13 for decoration; third, Mr. G. Mackinlay, Wroest Park, with a total of 91½.

There was a good entry for twelve dishes of fruit, grown in Scotland, and Mr. W. Hunter, Yester, won, Mr. J. Kidd, Carbery Tower, being second, and Mr. J. M. Stewart, Mollance, third, all with fine fruit.

In the collection of twelve dishes of fruit, grown in an orchard-house, Mr. G. Mackinlay was awarded the first prize. The smaller classes for Grapes were very good, and the winners of first prizes were Mr. J. J. Wann, Mr. W. Campbell, Mr. W. Galloway, Mr. T. M'Phail, Mr. J. H. Goodacre, Mr. J. Middleton, Mr. S. Gordon, Mr. L. Moodie, Mr. D. Kidd, Mr. G. Anderson, Mr. J. Dixon, Mr. J. E. Davis, Mr. D. Halliday and Mr. J. M. Stewart. Mr. Goodacre and Mr. A. Williams led for Melons; Mr. J. Wood for Figs; Mr. J. H. Goodacre for Peaches; Mr. J. K. Brown for Nectarines; and Mr. W. G. Pirie for Apricots. Mr. J. H. Goodacre had the best collection of dessert, and Mr. S. Gordon of culinary Plums, Mr. J. Wood, Mr. G. M'Glashan, Mr. R. G. Sinclair, Mr. J. Duff and Mr. J. Borrowman winning in their Plum classes, these being very good indeed. Apples were strong classes, and were so numerous that details cannot be given, but Mr. R. Whiting was first for the collection of twelve varieties, Mr. J. Duff winning in a similar class for fruit grown in Scotland. Pears were fine, and the honours in the open class for the collection went to Scotland this time, Mr. R. R. Greenway, Benmore, being first. For a collection confined to Scotland Mr. W. Galloway was first.

The plants were of high quality, but no prize was offered for a group, and the classes were thus comparatively unimportant, though drawing out excellent exhibits. Mr. J. M'Neil had the best four stove or greenhouse plant; in flower; Mr. A. Jels the best Orchids; Mr. J. M'Neil the best exotic Ferns; Mr. A. M'Millan the best foliage plants, exclusive of Palms, and the best six table plants, Mr. W. T. Galloway led with tuberous Begonias, and Mr. W. Page with Chrysanthemums.

Cut flowers were of wonderful quality, considering the season, and reflected great credit on the numerous exhibitors, only a small number of whom can be named at present. In the open classes Messrs. G. Mair and Son occupied their wonted high position with Gladioli. Mr. J. Smellie won the first prize for Cactus, and Mr. J. Paul for Pompon Dahlias. Messrs. J. Cocker and Son led with thirty-six Roses, distinct, with very beautiful flowers; second, Messrs. D. and W. Croll; third, Mr. W. Ferguson. Mr. R. C. Ferguson had the best Hybrid Tea Roses, and Messrs. D. and W. Croll received the first for eighteen Teas. For twelve vases of exhibition Roses, and also for twelve vases of decorative Roses, Mr. W. Ferguson was first, the same exhibitor carrying off the premium for a collection of Roses. With grand flowers Mr. W. Smellie won for early Chrysanthemums.

In the gardeners' classes Mr. John Fletcher, Auchensweeth, Lanarkshire, practically swept the boards with his Sweet Peas, which won for him the firsts in the classes for twelve and six bunches, and for a new variety not in commerce. Mr. J. Stewart, jun., led for Gladioli; Mr. C. Shaw for Cactus Dahlias; Mr. J. Simpson for twenty-four Roses and for twelve Teas; Mr. J. Mathison for twelve Hybrid Tea Roses; Mr. C. Kay with Pansies; Mr. W. Boyes with Violas; Mr. W. G. Pirie with herbaceous flowers; and Mr. W. Young won the first for his collection of cut flowers grown in the open. Other classes cannot be detailed.

Vegetables were not so numerous as we have seen at some previous shows, and the quality seemed a little more irregular than usual, though, as a rule, very fine. For the collection of eighteen dishes Mr. W. Young, Craighlaw, led; second, Mr. J. E. Davis. In the class for a collection of twelve dishes, grown in Scotland, Mr.

C. Shaw, Boquhan, led, with Mr. W. P. Bell and Mr. R. Stuart respectively second and third.
The amateurs' classes were not specially strong, although comprising a number of good exhibits.

TRADE EXHIBITS.

Trade exhibits always lend a high attraction to this show, and, although a few prominent firms who had exhibited at Glasgow did not send this season, the display was a magnificent one.

Messrs. Dobbie and Co., Edinburgh, exhibited a grand lot of flowers, making a special feature of their Collarette and Paony Dahlias, which were extremely fine; magnificent Sweet Peas, Roses and other flowers. These formed a great centre of attraction. Gold medal.

Messrs. Storie and Storie, Glencarse, Perthshire, set up a fine display of fruit trees in pots, Celosias, Carnations, cut fruit and other subjects, including their Excelsior Iceland Poppies. Their *Præcox* Carnations, from seeds sown in February, and their strain of Celosias were much noticed. Silver-gilt medal.

Messrs. W. Cutbush and Sons, Highgate, London, staged a magnificent group of hardy flowers of great interest, together with dwarf and standard Polyantha Roses. Silver-gilt medal.

Messrs. R. Wallace and Co., Colchester, contributed a capital display of hardy flowers, Gladioli and Montbretias M. Star of the East, a magnificent flower, received great attention. Silver medal.

Messrs. E. Webb and Sons, Wordsley, staged a selection of their specialities in vegetables and flowers of the highest quality, and excellently displayed. Silver-gilt medal.

A fine variety of Gladioli of the different classes was sent by Mr. S. A. Jones, Kilkenny. Silver medal.

Mr. John Downie, Edinburgh, contributed a table of Begonias, Gloxinias and other flowers in fine strains. Silver-gilt medal.

Another Edinburgh firm, Messrs. Tillie, White and Co., staged a fine lot of vegetables, Gladioli, Lilies, &c. Silver medal.

Mr. David W. Thomson, Edinburgh, sent a capital exhibit of Gladioli, embracing the leading sections of this handsome flower in varieties of the highest quality. Silver-gilt medal.

Messrs. John Forbes, Hawick, Limited, as usual, made a fine exhibit with their florists' and other flowers, their stand showing Phloxes, Pentstemons, Dahlias, Carnations, &c., in the most modern types. Silver medal.

A striking display of hardy border and other flowers was sent by Mr. D. O'Mish, Crieff, and we observed among these a number of excellent Delphiniums, early Chrysanthemums and other flowers. Silver medal.

Hardy flowers were well represented in the exhibit of Messrs. G. Gibson and Co., Bedale, a considerable number of flowers of merit or novelty appearing in the stand. Silver medal.

Carnations formed the contribution of Messrs. Young and Co., Hatherly, who, as usual, sent a variety of good flowers of the most advanced Perpetual-flowering types. Silver-gilt medal.

Messrs. Cunningham, Fraser and Co., Edinburgh, contributed two fine groups to the show. The first was composed of hardy flowers, Roses, &c., and the other of Hollies—a speciality—and other shrubs and trees. Silver-gilt medal.

A very attractive group of conifers, &c., was set up on the floor of the hall by Messrs. R. B. Laird and Sons, Limited, with which is incorporated Messrs. James Dickson and Sons, Edinburgh. Silver medal.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex, made a good show with choice Orchids and Carnations, with Apples and other produce of fine quality. Silver medal.

The exhibit of Messrs. James Cocker and Sons, Aberdeen, consisted of an effective and choice stand of hardy border and other flowers. Silver medal.

Messrs. T. Methven and Son, Edinburgh, had a nice group of Lilies, Clematises and other hardy greenhouse plants. Silver medal.

Tree Ivies in the most varied display formed the grand group from Mr. L. R. Russell, Richmond. Silver medal.

The King's Acre Nurseries, Hereford, sent a grand array of Apple and other fruit trees in fruit. Silver-gilt medal.

Messrs. E. F. Fairbairn and Son, and Messrs. G. Fairbairn and Sons, Carlisle, showed Cactus and other Dahlias with Carnations, &c. Bronze medal to each.

Peony-flowered Dahlias were grandly staged by Messrs. Bakers, Wolverhampton. Silver medal.

Messrs. W. Thomson and Sons, Clovenfords, showed Grapes, &c., for which a silver gilt medal was awarded. Sweet Peas were finely exhibited by Mr. R. Bolton, Warton, Carnforth. Bronze medal.

An interesting table of Ferns, Lycopods, &c., with refined Lily of the Valley, came from Mr. H. N. Ellison, West Bromwich. Silver medal.

Messrs. T. Kennedy and Co., Dumfries, sent an exhibit of hardy flowers, Sweet Peas, Dahlias, &c. Bronze medal. Phloxes were well shown by Messrs. Gunn and Sons, Olton. Bronze medal.

Messrs. Little and Ballantyne, Carlisle, staged a fine lot of Apples, &c., all cut from the open. Silver-gilt medal.

From Dundee, Messrs. Thyme and Sons sent a grand lot of Sweet Peas, border flowers, annuals, &c. Silver-gilt medal.

Mr. R. C. Ferguson, Dunfermline, had a varied display of the best Roses. Bronze medal.

Messrs. Mason and Co., Jamestown, staged Pansies, Violas, Chrysanthemums, &c. Bronze medal.

Messrs. W. Wells, Limited, Merstham, had one of their attractive exhibits of early Chrysanthemums, including

Crimson Polly, which has received so many awards this season. Silver medal.

Messrs. T. S. Ware, Limited, Feltham, made a grand display with Begonias, among which Lady Cromer was conspicuous. Silver-gilt medal.

The Edinburgh and East of Scotland College of Agriculture exhibited preserved fruit and specimens of their publications. Bronze medal.

Mr. G. W. Miler, Wisbech, sent Apple Miller's Red Victoria, to which an award of merit was made. Bronze medal.

Mr. Muir, Lindlithgow, exhibited a number of good *Cypripediums*. Silver medal.

Messrs. Sander and Sons, St. Albans, staged a very choice table of Orchids, which included some splendid new varieties. Silver-gilt medal.

Mr. McLeod, Charlton-cum-Hardy, sent a choice lot of Orchids, which were also awarded a silver-gilt medal.

The following other awards were made:
First-class Certificate.—To Montbrétia Star of the East, from Messrs. R. Wallace and Co., Colchester.

Awards of Merit.—To Messrs. Dobbie and Co., Edinburgh, for each of the following: Collarette Dahlias Prince John, Princess Louise and Frogmore, Cosmosses White Queen, Rose Queen and Crimson Queen; Mr. D. W. Thomson, Edinburgh, for Apple Thomas Jeffrey; Mr. G. N. Simpson, Edinburgh, for Tomato Simpson No. 1; Mr. W. Wells for Chrysanthemum *Crimson Polly*; Mr. Fulford, Montgomerie Castle, for Pentstemon Mrs. F. Fulford; Messrs. Mason and Co., Jamestown, for Chrysanthemum Mrs. Mason; and Messrs. J. Cocker and Son, Aberdeen, for Hybrid Tea Rose Mrs. A. Carnegie.

Other exhibits included those of "Gardenalities," Mr. Edwards, the Patent Safety Ladder Company, and Hughes, Bolekov and Co.'s garden furniture.

NATIONAL ROSE SOCIETY.

AUTUMN SHOW.

A MAGNIFICENT display of autumn Roses was to be seen at the National Rose Society show, held in the Royal Horticultural Hall, Vincent Square, Westminster, on September 12. At no previous autumn show have we seen large groups of Roses of such good quality and staged with more consummate skill and taste. These large groups were unmistakably the chief feature of the exhibition, and the banks of well-coloured Roses were pleasing in the extreme. Baskets and vases of Roses, as well as blooms shown on boards, came in for great praise from the admiring public, and the Rose haps, which are so interesting at this season, were well represented in the classes allotted to them. A general review of the show, together with descriptions of new seedling Roses, will be found on page 476 of this issue.

NURSERYMEN'S CLASSES.

There was very keen competition in Class 1 for thirty-six blooms, distinct. Messrs. Hugh Dickson, Royal Nurseries, Belfast, secured the premier award with a remarkably good lot of exceptional colour and substance for the time of year. This board contained particularly fine blooms of *Caroline Testout*, *Lady Alice Stanley*, *W. R. Smith* and *Hugh Dickson*; second, Messrs. J. W. R. Smith and Son, Gloucester. This board was much strengthened by exquisite blooms of *Lyon Rose*, *J. B. Clark* and a well-coloured, but rather thin bloom of *Lady Hillington*. Third, Messrs. J. Cocker and Sons, Aberdeen; fourth, Messrs. Adam and Craigmillie, Rubistaw, Aberdeen.

The first prize in Class 2 for twelve blooms, distinct, was won by Mr. Henry Drew, Longworth, Berks, who showed *Mme. Constant Souperet* and *Souvenir de Pierre Notting* in grand form. Mr. George Prince, likewise from Longworth, was a good second. His stand contained perfect blooms of Mrs. Foley Hobbs, *White Maman Cochet* and Mrs. E. Mawley. Third, Mr. John Pigg, Royston, Herts.

Mr. John Mattock, Headington, was first for nine baskets of cut Roses, showing lovely baskets of *Caroline Testout*, *Hugh Dickson* and *Mrs. Sharnan Crawford*.

In a similar class for nine baskets Messrs. Hugh Dickson, Limited, Royal Nurseries, Belfast, led the way with magnificent baskets of *Lady Pirrie*, *Irish Elegance*, *Betty* and others; second, Mr. John Mattock; third, Messrs. S. Bide and Sons, Farnham, whose basket of *Rayon d'Or* was the admiration of all visitors.

Messrs. W. Spooner and Sons, Woking, were first for five baskets, in which *General Macarthur* stood out prominently; second, Mr. J. C. Crossing, Penarth; third, Mr. H. Drew, Longworth. An extra prize was awarded to Mr. E. J. Hicks, Twyford, Berks, for five very beautiful baskets in this class.

For a basket of twelve blooms Messrs. Frank Cant and Co., Colchester, led the way, closely followed by Messrs. Hugh Dickson and Messrs. McGredy and Son in the order named.

Mr. J. Mattock of Headington, Oxford, scored a triumph in carrying off the first prize for eighteen varieties, distinct. Messrs. Frank Cant and Co. were second.

For nine vases of decorative Roses, Mr. E. J. Hicks took the premier place, showing, among others, three very pretty vases of *Lady Pirrie*, *Lyon* and *Comtesse du Cayla*; second, Mr. Will Taylor, Hampton; third, Messrs. G. and W. H. Burch.

For twenty-four varieties shown in vases, Mr. J. Mattock was first with a grand lot, including *Mme. Jean Dupuy*, *Lady Hillington*, *La Tosca* and *M. Paul Lede*. Messrs. Frank Cant and Co. and Mr. John Pigg were second and third respectively.

Messrs. W. Spooner and Sons, Woking, were first in Class 10 for twelve decorative Roses, their blooms of

Souvenir de M. de Zayas, *Lady Pirrie* and *Miss Dorothy Nocatta* being much admired. Mr. George Prince was a good second, followed by Mr. E. J. Hicks.

Mr. George Prince was more successful for twelve varieties of Dwarf Polyantha Roses, carrying off the first prize. Messrs. W. Spooner and Sons, Woking, and Messrs. B. R. Cant and Sons, Colchester, were the runners-up.

Hobbies, Limited, Norfolk Nurseries, Dereham, were successful in securing the gold medal and first prize for a representative group of Roses arranged on the floor. It was an admirable group and well arranged. Messrs. Paul and Son, Cheshunt, were second with an almost equally good exhibit.

Undoubtedly the finest exhibits in the show were those in Class 13 for a group of Roses on staging. The exhibitors in this class quite excelled themselves in their manner of staging, and the quality of the blooms left little to be desired. Messrs. Gunn and Son, Olton, Birmingham, were first with a gorgeous display, staged in a masterful way. In the background of this group were arches of Rambler Roses, with pillars of blooms surrounding a magnificent centre-piece of the *Lyon Rose*, *Molly Sharnan Crawford*, *A. R. Goodwin* and *Frau Karl Druschki* were prominent among a truly grand collection of varieties. Gold medal. The second prize and silver-gilt medal fell to the lot of Messrs. W. and J. Brown, Peterborough, who staged an even higher lot of arches and pillars, with baskets of Roses in the foreground. The third prize and silver medal were won by Mr. G. Prince for a group of exceptional quality, among which a pillar of *Rayon d'Or* was the centre of admiration. An extra prize was deservedly awarded to Messrs. Benjamin R. Cant and Co. in this class.

Messrs. Harkness and Co., Hitchin, were first for a group of cut Roses (Class 14) with a rather informal group, artistically arranged with baskets of *Lyon Rose*, *Mme. Abel Chateau* and *Lady Hillington* in the foreground. Mr. F. M. Bradley was second, whose group contained a charming combination of colour with *Lyon Rose* and *Irish Elegance*. Messrs. Jackman and Son, Woking, were third. We were well impressed with a new semi-double Hybrid Tea named *Cherry Page*. It is of a brilliant cerise colour, shading to apricot, and was shown in the group staged by Mr. Walter Eastlea, Eastwood, Essex.

For thirty-six varieties, not fewer than three trusses of each. Messrs. Frank Cant and Co. led the van with such capital varieties as *A. R. Goodwin*, *Alice Roosevelt*, *Gottfried Keller* and *Papa Gontier*. Mr. J. Mattock and Messrs. J. Jefferies and Son were second and third respectively.

Considerable interest was displayed in the class for the haps of nine species or varieties. Among those shown we observed the following: *Atropurpurea*, *Sweet Briar*, *rugosa rubra*, *Red Scots* and *Lennox Scots*, the last two having black fruits. Messrs. Benjamin R. Cant and Sons were first in this class, followed by Messrs. Paul and Son, Cheshunt, and Mr. George Prince.

AMATEURS' CLASSES.

There was good competition in almost all, if not quite all, of the amateur classes. The blooms shown on boards were of good average quality, although here and there there were unmistakable signs of weather-beaten blooms. Nevertheless, the exhibits were a credit to the exhibitors, and we were pleased to note that the blooms on boards were not over-dressed, a failing in which the nurserymen had erred sadly. The bowls and baskets shown by amateurs formed one of the most pleasing features of the show. That well-known exhibitor, Mr. Conway Jones of Huclecote, Gloucester, was most successful on this occasion, and his long list of successes included firsts in the following classes: Eighteen blooms, distinct; nine blooms, distinct; seven varieties in vases, three baskets of cut Roses; twelve varieties, not fewer than three trusses of each; and group of decorative Roses (Class 31), besides two medals for the best blooms in the show. His blooms of *Mme. Wagram*, *White Maman Cochet*, Mrs. Foley Hobbs and *Medea* were perhaps the pick of a very fine lot.

Mr. F. Speight, Market Harborough, was first for twelve blooms (Class 20), and Mr. J. Moulles, Hitchin, led the way for nine blooms in the class following with particularly good flowers of *W. R. Smith*, *Mildred Grant*, *Mrs. E. Mawley* and *Caroline Testout*.

In the class for six blooms, distinct, Mr. W. P. Panckridge, Petersfield, was first, showing blooms of exceptional size of *Lady Ursula*, *Frau Karl Druschki* and *Florence Pemberton*. The same exhibitor was first for five varieties shown in vases. Among other successful amateur exhibitors were the Rev. J. H. Pemberton, the Rev. F. Page-Roberts, the Rev. F. R. Burnside, Messrs. L. P. Roberts, S. W. Burgess, H. R. Darlington, Edward Mawby, E. B. Lindsell, G. A. Hammond and F. Slaughter.

The table-decorations shown in the Lecture Room on the first floor provided some of the most charming colour studies that we have ever seen. It was remarkable to note with what good taste the single Rose *Irish Elegance* could be used. It was this variety that dominated at least half of the tables in competition. The first prize was won by Mrs. Robinson, Park Hill, Carshalton, with a graceful table comprising the *Lyon Rose* and *Irish Elegance*. The colours of these two varieties enter into perfect harmony. Rose foliage and light Asparagus plumes were used as foliage. The second and third prize tables were both composed of *Irish Elegance*, with its own foliage, and were shown by Mrs. Hale, Warminster, and Mrs. J. W. Smith, Bushy Heath. An extra prize for a table decorated with the new variety *Sunburst*, with *Maidenhair Fern* and *Rose foliage*, was awarded to Mrs. Bide, Uxbridge.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Notes on Newer Roses.—Those of our readers who are keenly interested in Roses will be pleased to learn that we have persuaded Mr. H. E. Molyneux to once more contribute his "Notes on Newer Roses." The first instalment of these notes will appear in our next issue.

A Pretty Autumn Effect.—When visiting the gardens at Carrow Abbey, Norwich, a few days ago, we noticed a narrow border, running alongside a warm greenhouse, filled with Amaryllis Belladonna and edged with the pretty little New Zealand Windflower, Zephyranthes candida. Although the Amaryllises were not out to perfection, enough were there to indicate that the combination of these two plants would be excellent, the white, star-like blossoms of the Zephyranthes harmonising well with the soft pink of the Amaryllis. The narrow, deep green foliage of the Zephyranthes also tended to take away the bareness of the soil that is always an eyesore when the Amaryllis is grown by itself.

A Woodland Bed in Autumn.—Those who are thinking of planting large beds of flowers by woodland pathways would do well to consider the merits of the stately Kniphofias or Torch Lilies for the purpose. A short time ago we noticed a very beautiful effect created by the use of that excellent Torch Lily John Benary. A large bed had been made in the grass by the side of a long, gravel pathway, and just behind the bed was a lofty Beech tree with a large, clean trunk. The bed had been filled with the Torch Lily, and the effect, when seen from a distance, was very pleasing indeed, the trunk of the Beech tree appearing to rise out of the bed of flowers. An Ash, Chestnut, or even an Elm tree would produce much the same effect, providing the trunk was clear of branches and the bark moderately smooth.

Colchicums and Autumn-flowering Crocuses in Grass.—Although everyone who has a garden of any pretensions tries to produce a beautiful floral feature during the early months of the year by naturalising bulbs in grass, few people take advantage of the autumn-flowering Crocuses and Colchicums to produce a similar effect in September and October, yet a very striking picture may be made by their aid. Planted among grass they thrive quite as well as the spring-flowering kinds, and require similar treatment. The colours vary from crimson to white in the Colchicums, and from blue to yellow and white in the Crocuses. Colchicum autumnale and its varieties C. speciosum, C. byzantinum and C. variegatum may all be used, while good Crocuses are C. speciosus, C. longiflorus, C. pulchellus, C. sativus and C. asturicus. Some bulb-dealers make a speciality of supplying mixed hulbs of both genera for naturalising.

Campanula carpatica White Star.—This is certainly one of the finest of the turbinate section of the bell-flowering family, flowering in late August and continuing into September. Save for a goodly suffusion of blue, which is always increased with age, the flowers are almost white, and at a short distance pass muster as such. In any case it is a good plant, not much more than 9 inches high when in full vigour and very freely flowered. Like many another of the same race, it loves a cool spot and a rather strong loamy soil. The flowers are nearly two inches across.

The Gardens at Regal Lodge, Kentford.—In the description of these gardens, which appeared in our issue for September 7, we omitted, owing to a misunderstanding, to mention that some of the main features, including the loggia, Lily tank and sunk garden, the paved terrace, herbaceous borders and pleached alleys, were originally planned by the Hon. Mrs. Grosvenor, whose skill as a garden artist is well known. Although we understand that considerable alterations have been effected in the gardens by Lady de Bathe since they were originally designed, we think it is only right that credit should be given to the Hon. Mrs. Grosvenor for her excellent initial work.

A Good Trio of Dahlias.—Many of the numerous varieties of single Dahlias are unsurpassed for garden decoration. For profusion of blossoms their closest rivals are the Pompon section. As they seed freely, it is very necessary to remove the old flowers at frequent intervals. For beds and borders three of the best single Dahlias grown are White Queen, Miss Roberts (rich yellow) and Rosebank Cardinal (red). All three average from 4 feet 6 inches to 5 feet in height. The flowers of the yellow and red varieties are about three inches across, those of the white rather more.

The French Gorse.—In many parts of the country the French Gorse (Ulex Gallii) is very effective at the present time, for, in company with Ling and Heather, it brightens up many a common and hillside. U. Gallii may be easily recognised not only by its flowering in autumn, but by its habit being dwarfier and more compact than that of U. europæa. On some of the commons in the Southern Counties, where the young shoots are cropped off by sheep, it becomes in time quite dense and forms round, cushion-like masses a foot or so high. These at the present time are a mass of gold, for the fact of the shoots being injured occasionally does not appear to affect the flowering. Apart from its beauty in a wild state, it is an excellent plant to introduce into the garden, especially where a dry bank has to be covered, for it may be grown successfully in quite poor soil, and if cropped over once a year may be induced to adopt the stunted character, in which condition it is seen to advantage. By mixing it with Heather and Ling in irregular fashion, a charming natural effect is obtained.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Hardy Japanese Shrub.—In the September 7 issue of THE GARDEN, page 447, Mr. S. Arnott would like to know of the hardiness of *Cercidiphyllum japonicum*. It is such a beautiful and graceful shrub that one would be more than sorry to hear it was not hardy. A plant growing here has shown no signs of being in any way tender. The plant is about five feet high and four feet through, making a lovely bush and vigorous growth. It was unhurt by 24° of frost last winter, and came through late spring frosts unscathed when *Kalmias* and *Azaleas* were nipped. Winds have had no effect on the plant here, but certainly it is to some extent sheltered from north and east.—W. D. BESANT, *The Curragh Grange Gardens, The Curragh, County Kildare.*

A Cheerful Autumn Flower (*Sternbergia macrantha*).—There is no more cheerful-looking flower in our gardens in autumn than *Sternbergias*, with their bright yellow Crocus-like flowers. *Sternbergia macrantha*, which is now in bloom, is undoubtedly the finest of the whole genus; it differs from the familiar *Sternbergia lutea* in its larger flowers, long perianth tube, and in producing leaves in spring, instead of with the flowers in autumn. In its native habitat it is very widely distributed, extending from Persia to the east as far as Smyrna, and southward as far as Jerusalem. It is an excellent plant for pots in a cool greenhouse, and equally as good for a sheltered border outside or a sunny nook in the rock garden.—F. G. P.

Crocus Species and Rare Shrubs.—I see in September 14 issue, page 461, an article signed "P. J.," in which he writes of not finding the species *Crocus* in any of the trade lists. He may like to know that Messrs. Barr have them catalogued in their ordinary bulb list, as well as issuing a special list, and a very comprehensive one, in the summer. I thoroughly endorse all that "P. J." says of these Crocuses. Personally, I greatly prefer them to the Dutch varieties. They look very well, as I have them, as a thick carpet to *Erica carnea* and *E. mediterranea hybrida* in small beds in a paved garden for winter effect. I have also recently seen correspondence questioning the hardiness of certain shrubs, such as *Choisya*. My experience may perhaps reassure those who hesitate about planting them. I live on the top of a hill, where we seem to be exposed to every wind that blows. The soil is a cold, clinging clay. I am an absolute amateur, do not employ a trained gardener (only a labourer for trenching work), and had never had anything to do with gardening until I determined to make a garden out of our wilderness here five or six years ago. So, if I can succeed, I am sure anybody can, especially as I do not by any means devote all my time to it. I have every piece of ground where I am going to plant bastard-trenched to a depth of 3 feet. Where the soil is very bad, I fully trench it 3 feet deep. I lighten the soil with leaf-mould, mortar rubbish, lawn-mowings, vegetable refuse, horse-manure, and I burn some of the clay and turn it into red earth. Of course, special plants get special diet. The others have to lead the simple life and put up with a merely trenched soil, as I have to be very economical in the matter of manures, leaf-mould, &c. *Solanum crispum*, which I planted as a little thing about five years ago, is now over eight feet high and as much through. I protected it

the first two years with matting in the winter, but since then it has been too big to do anything with, so I have left it alone. I have also two fine bushes of *Choisya ternata*, which are never protected and flower beautifully; also one *Fremontia californica*, which grows in the same border as the *Choisya*, protected from north and east and open to the south. *Olearia Gunnii*, also in the same border, is likewise a mass of bloom in early summer. It is very effective with a grouping of *Iris*s near it.—ST. PAUL'S WALDEN.

Hardy Fuchsias.—With the exception of *Fuchsia gracilis* and *Fuchsia Riccartonii*, the several hardy varieties do not get the attention they deserve, as they are all exceedingly beautiful, and there is now a great variety to be found among them. Mr. L. R. Russell of Richmond has at some of the recent meetings of the Royal Horticultural Society shown us the numerous forms that are at the present time available. As pot plants, however, beautiful though they be, they do not appeal so markedly to one as when they are planted out in the open ground. During a visit paid a few days ago to Messrs. Veitch's nursery at Coombe Wood, my attention was arrested by the beauty of the hardy Fuchsias. There a long, undulating border, planted with an extensive collection of choice shrubs, was lit up here and there with numerous specimens of the hardy varieties of Fuchsias, which supplied a wealth of colour when most of their associates were out of bloom. Besides the two varieties mentioned at the head of this note, such kinds as *americana elegans*, *corallina* or *exoniensis*, *coccinea*, *globosa* and *Thomsonii* were noted. Some of M. Lemoine's hybrids were also conspicuous, especially *Enfant Prodigue*, with fairly large, semi-double flowers, whose sepals are red and the corolla purplish. Mme. Cornillon, sent out about fifty years ago, arrests attention by the fact that it is the only hardy variety with a white corolla.—H. P.

Sweet Pea White Queen.—I always read the Sweet Pea notes by Mr. Horace J. Wright in your valuable paper with particular interest. Mr. Wright speaks of bewilderment in approaching lists of varieties, and it is with reference to one of the newest of these, viz., *White Queen*, that I would refer to his remarks on page 466, issue September 14. The merits of a white Sweet Pea are more easily understood on paper than those of any colour, and Mr. Wright says of *White Queen* that the form of the flower is excellent, and that the blooms are admirably set on the stem, and that the plant is a thoroughly good grower. May I ask in what way these virtues render *White Queen* conspicuous or new? I am sure you will acquit me of any desire to obtain free advertisement when I say that *Paradise White Pearl* is in my mind as having, since its introduction two years ago, already brought these advantages and more before the public. By the "more" I refer to purity and substance. The former is certainly not a feature of *Moncymaker* and others, while substance all the old waved whites have lacked, and I am sure that *White Queen* lacks it also unless, *mirabile dictu*, it has the same pedigree as *Paradise White Pearl*. To give you and your readers an opportunity of judging how far my claim is likely to be well founded, I am willing to disclose the pedigree of *Paradise White Pearl* if the introducer of *White Queen* will do the same. It is not without hesitation that I make this offer, but I am so curious to know whence *White Queen* gained in substance that I am willing to disclose my little secret.—HILDA HEMUS.

Rose Sunburst.—In answer to your correspondent "G. T. W.," page 474, issue September 21, I have found this *Rose* varies greatly in colour and quantity of petal. My first crop came thin, but the most beautiful colour, i.e., richest apricot; the next full in petal, but outer bleached halfway down (the exceptional weather may account for Blossoms grown under glass are not always free from this fault. I shade immediately the buds show colour. This to many may be against this *Rose*, but to catch its intense apricot hues amply repays. If your correspondent is fond of yellow *Roses* and has not grown *Alice Rothschild*, *Mabel Drew* and *A. H. Grey*, might I strongly recommend him to do so, as I have found them splendid growers, the flowers of excellent shape and plenty of them, lasting well in water, good resisters of mildew, especially the last-named, and, what is most exceptional with yellow *Roses*, the colour does not "fly," but deepens with expansion.—WEST WORTHING.

The Sporting of Californian-grown Sweet Peas. The subject of the sporting of Californian Sweet Peas, raised by several correspondents, is one of interest to all lovers of this flower. Why, however, limit the observations to Californian Sweet Peas only? I ask this question because, until I hear of conclusive evidence to the contrary, I shall believe that the same laws governing this matter hold in California as they do here. One has often seen it advanced that different insects abound abroad to what are seen here, and that they may have a different way of working to those in our own country. Personally I cannot follow this, as even if they do work differently and actually enter the flowers and carry away pollen to other flowers, my experience, of many years' standing, teaches me that they might bring about cross-pollination but not cross-fertilisation—a very different matter. The fertilisation has taken place before this pollen is transferred, and would have no more effect than so much inorganic dust. I have never, in all my experience, come across a case of "sporting" which I could trace to natural cross-fertilisation. There is a lot of nonsense talked about insects and their effect upon cross-fertilisation. I admit they do bring it about in many flowers, but it is much rarer than is supposed. Is it likely that Nature would rely upon the chance visitation of an insect to ensure the perpetuation of any species of plant? Nature does not believe in the haphazard. We have been so accustomed to take for granted all we read of the conclusions of such men as Darwin that we have, very few of us, taken the trouble to see whether such conclusions are correct. Eminent scientific writers have done the same, hence too much stress has been laid upon the importance of insects to flowers. Because Darwin and others have noticed certain things to take place at different times they have concluded that it always happens, and is the universal law of Nature with regard to the particular plants observed. This, however, is a digression. I think several of your correspondents hit the nail on the head when they infer that there is not as much care shown in the growing of Californian stocks as in this country. They are grown without sticks upon a huge scale, and cannot be as carefully superintended. Growers know well that one has to pass along rows scores of times before all rogues come out. You might miss one many times. If this is so when grown upon sticks, what about those growing low down, to which the Chinaman has to bend in the heat of a scorching sun. Is it to be wondered at that many are left?—H. E. WARD.

Schizanthus grandiflorus maximus (Dr. Badger's hybrids).—Under this name an exhibitor sent a number of varieties of *Schizanthus* to the recent Edinburgh show. No particulars were attached, and no information was forthcoming as to the parentage of these flowers. They are large and well coloured, but do not show any signs of hybridising. Are not these simply selected varieties?—VISITOR.

New Early-flowering Carnations for the Border.—Quite a feature of the fine exhibit of the Scottish firm of Storrie and Storrie at the recent show of the Royal Caledonian Horticultural Society in Edinburgh was a group of what were called "Præcox Border Carnations." A large number of plants were shown, these being raised from seeds sown in February, and which have been in flower for some time. Included in the exhibit were several boxes, into which a number of the plants had been pricked out 2 inches apart from the seed-pans. These were in flower also and producing really good blooms. As compared with the Marguerite Carnations, to which these flowers would seem related, the Præcox varieties are much better in form and have more refined flowers. The colours are extremely varied, and a special feature one observed was the small proportion of single flowers, even among the plants which had been left in the seedling-boxes. Mr. David Storrie may be congratulated on these Præcox Carnations.—S. A.

The Original China Aster.—Until a few years ago the type of the various cultivated forms of the China Aster (*Callistephus hortensis*) was practically unknown in our gardens, for although it had been grown many years ago, the double-flowered varieties had quite supplanted it. Upon its reintroduction it quickly found favour with horticulturists, for its elegant habit and large heads of flowers, composed of pretty mauve ray and yellow disc florets, made a very pleasing combination. Moreover, it was found to offer excellent possibilities for landscape effect when sown with a generous hand in the wild garden, and many extensive areas have been seen covered with it in autumn at Kew and in other gardens within recent years. When first reintroduced it came quite true from seeds, but a few years' cultivation appears to have exerted some strange influence upon it, which makes the colour of the flowers vary considerably, and mauve, white, purple, pink and red forms may be obtained from a packet of seeds. A large mass near the Isleworth Gate at Kew may be seen in full flower at the present time, many shades of colour being represented. The effect is one which might well be copied by people who are fond of touches of colour in woodland scenery at this time of the year.—D.

ROCK AND WATER GARDEN.

THE BEST SAXIFRAGES AND HOW TO GROW THEM.

(Continued from page 476.)

IN fulfilment of the promise made in THE GARDEN of the 14th inst., I will now briefly refer to some of the choicer sorts, best suited, by reason of their early flowering rarity, diminutive growth, or other good quality, for pot cultivation in frames, or, preferably, where such exists, to figure in that model, moderate, unheated structure we know to-day as the "alpine-house," and which year by year is becoming more essential in all gardens where the best of these plants are cultivated. This does not of necessity infer that protection of this or of any other kind for alpine vegetation is new—far from it, since growers of repute of forty years or more ago not only gave it, but regarded it as essential to the bringing out of all that is best in these plants. Such men as James Atkins of Painswick, Mr. Joad of Wimbledon, and Latimer Clark of Sydenham

protecting these plants was so simple that I have frequently recommended it, and do so again to those readers of THE GARDEN who love these alpine—and they must be a considerable number—and to whom the winter beauty of such things is only exceeded by their flowering.

Naturally, to those who can afford it, the alpine-house is far better, because the plant-lover is brought into closest communion with the flowers of his choice. In recommending a glass structure for alpine plants I know I am treading heavily on the corns of some hardy plantsmen who detest a glass covering of any description. But what of that! Is it better to expose them to all the changes and chances of an English winter, and to see them day by day bereft of all their winter beauty and charm, or to afford them the protection they need and enjoy the best they are capable of giving? Dame Nature in winter-time keeps these children of the mountain snug and dry and warm beneath a great coverlet of snow, while in this country during the same period they would probably be fog-smitten and rain-sodden for weeks on end, and of no beauty to be desired.

CHINA ASTERS IN THE WOODLAND.

Hill, pioneers and past-masters of alpine cultivation in their day, all afforded protection to their choicest and best, not because of any misguided notions as to the complete hardiness of the subjects, but because they first realised, and proved to demonstration afterwards, that only by some such means was it possible to have revealed the best the plants were capable of giving.

The first time I saw the Painswick collection was in winter, when the choicest of the Encrusted Saxifrage were sheltering in a frame composed of stout side planks 9 inches deep, and equally stout wooden ends, into which a grooved ridge was fixed centrally at 2 feet high for receiving the glass to form the miniature span-roofed greenhouse, or frame it really was. The angle formed would be 45° or more, so that all possible light was ensured. The plants were in pots and pans, each a delightful specimen of its kind, and, judged by an encrusted beauty I never forget, were apparently revelling in the clear, pure air characteristic of the favoured Cotswold village referred to. The method of

We do not grow these plants merely to test their powers of endurance, but to get all we can out of them and for the longest period of time, and the alpine-house is the best way. For such a structure the essentials are an open position and the fullest light and ventilation. There must be no misguided notions as to artificial heat, which is not only unnecessary, but is calculated to disfigure and to destroy. Damp, too, is a great and ever-present enemy of an English winter; hence the house should never be closed, but ventilated freely at all times. Under such conditions, success is more than half assured at the outset. Moreover, such a structure ranks high economically—no fuel, no heating apparatus, no frost or thermometer to study, and, best of all, none of the vile abominations of the oil lamp, from which so many plants grown in the warmed greenhouse of the amateur suffer to-day. A 25-foot-long by 10-foot-wide house will accommodate a host of alpine, and one-half the length quite a large collection. Details of size, however, are not for me to decide.

FORTHCOMING EVENTS.

October 1.—Scottish Horticultural Association's Meeting.

October 2.—National Vegetable Society's Show at Watford. National Chrysanthemum Society's Exhibition at the Crystal Palace (two days).

October 5.—Société Française de Horticulture de Londres Meeting.

To begin with, the amateur, if he would have specimen plants, should provide himself with a series of dwarfed pots or special pans, those having a depth of 5 inches and a diameter of 8 inches being suited to a large number. A well-made-up pan of an alpine should approximate as near as may be to a well-arranged colony on the rockery; that is, those of diminutive stature should be seen jutting out from between miniature pieces of rock, while the true carpeters, *Salomonii*, *apiculata*, *sancta* and others, should be permitted to clothe the entire surface of the soil. Even the *Aizoons*, robust and free of growth as they undoubtedly are, play quite a new role in the alpine-house, the silvery braided or hoary-leaved sorts being more pregnant of life and beauty. Such giants as *S. Cotyledon* and *S. longifolia* should be grown as single specimens in pots of the ordinary kind.

In the matter of soil, a gritty loam with perfect drainage will suit the majority, while the addition of much sand or old mortar will not be in vain. In the subjoined list will be found a selection of

THE ROSE WALK, PURLEY.

THOSE readers who are members of the National Rose Society will remember, perhaps, that under the heading of "An Interesting Experiment in Estate Development" I contributed to the "Rose Annual" for 1900 a short description of the above walk, then just completed.

Since that date the Roses have matured, and this season were particularly fine. The accompanying illustrations give one some idea of what was a continuous picture along both sides of a road some half-mile in length, and the general effect of which is easier imagined than described. At their best in the last three weeks in June and the first fortnight in July, still, at all seasons of the Rose year, namely, the six months from May to November, Roses are to be found, and it must be a source of continual pleasure and satisfaction to the original

I.—A PORTION OF THE ROSE BORDER AT PURLEY, SHOWING BLUSH RAMBLER AND DOROTHY PERKINS OVER RUSTIC FENCING.

the choicer kinds suited to alpine-house or frame, some of which occur also in the earlier articles on this subject. Those marked by an asterisk grow freely in sandy loam of a quite ordinary character. **Saxifraga Aizoon* in variety, **S. apiculata* (yellow), *S. aretioides* (yellow), *S. Boydii* (yellow), *S. B. alba* (white), *S. Borisii* (white), *S. burseriana major* (white), *S. b. Gloria* (white), *S. b. magna* (white), *S. casia* (white), *S. calyciflora* (crimson), **S. catalaunica* (white), **S. cristata* (white), **S. crustata* (white), **S. Cotyledon* in variety (white), *S. diapensioides* (white), **S. Elizabethæ* (yellow), *S. Griesbachii* (crimson), **S. Hostii* (white), *S. kolanatiana* (pink), **S. Kotschyii* (yellow), **S. lantoscana* (white), **S. l. superba* (white), *S. longifolia* (white), *S. marginata* (white), *S. oppositifolia* (all-red and white), **S. pectinata* (white), **S. rocheliana* (white), **S. r. coriophylla* (white), *S. scardica* (white), **S. sancta* (yellow), **S. Salomonii* (white), *S. Obristii* (white), *S. Paulinæ* (yellow), *S. squarrosa* (white), *S. valdensis* (white), **S. cochlearis* in variety (white), *S. thessalica* (reddish) and *S. Petraschii* (white).

E. H. JENKINS.

owner, and even more so to the many present owners, that the experiment, if it can be so called, has turned out such a great success.

As seen on my last visit (the day of the Purley Horticultural Society's show) one saw plenty of flowers that would have put to shame many of the Roses exhibited in the prize boxes in the tents close by, and the display of decorative Roses, climbers more particularly, perhaps, was exceptionally fine. Though many of the *wichuraianas* had yet to reach their highest phase of possible beauty, yet the first blooms were there and the promise of many more to come was apparent; in fact, the Roses generally looked (as all Roses should look and do look when and where they are properly cared for) in robust health and vigour, thoroughly enjoying the conditions under which they were growing and returning thanks for the same in their unspeakable but none the less impressive fashion. I close with a brief description of the Rose walk and how it was formed.

Within a mile of Purley Station and less than thirty minutes' railway journey from Charing Cross,

on a plateau at a considerable elevation, has been formed a road some half-mile in length, on each side of which have been planted some thousands of Roses. Admittedly the site, an old pasture of many years' standing, was a favourable one, with a stratum of clay (light) over a subsoil of chalk. The whole of the top spit was removed from the surface of the road, and beds were formed some twenty-five feet wide throughout the entire length of the road, with alternate layers of loam, clay and manure, the whole thoroughly mixed. With this careful preparation success was deserved, at any rate. The road itself was extremely well made, the idea being to form the finest carriage-way in the district, and all sewers, gas and water mains, electric light cables and telephone wires have been laid in it to prevent that constant picking up so detrimental to newly-formed roads. I mention this to show what care and attention was bestowed on the whole scheme. The road is 40 feet wide, with wide paths, which have sloping grass banks, at the top of which is a light wire fence, then a grass walk (for private use only) and then the Rose-beds. The Roses have been planted in the following manner: At the back, climbing Roses on pillars and supports (see illustration No. 1), with an occasional weeping standard (see illustration No. 2), planted about six feet apart. Three feet in front of them are standards, half-standards, dwarf pillars and stronger-growing bushes. The second row consists of dwarfs of all kinds, exhibition, garden and decorative varieties; and the front row, *Chinas*, *Pompons* or *Dwarf Polyanthas*, and the dwarf-growing *Hybrid Perpetuals*, *Hybrid Teas*, &c. Planted in 1907, they have grown well, and the road is worth going a long way to see. Among other interesting features are the picturesque cottages at each end adjoining the gates, one a typical Surrey cottage, the other Sussex.

These notes are written in the hope that other landowners may copy the idea and so increase the culture of our national flower.

Southampton.

H. E. MOLYNEUX.

THE FLOWER GARDEN.

EARLY-FLOWERING OUTDOOR CHRYSANTHEMUMS.

THE few enthusiastic growers of the eighties are largely responsible for what we see of the early-flowering outdoor Chrysanthemums to-day. Notwithstanding the fact that the exhibits which were put up in the earlier days were often described by many as dull, dowdy and uninteresting, they were the beginnings of better times, as subsequent events so emphatically proved. M. Simon Delaux, a French raiser, used annually to send out batches of so-called early sorts, but few of these were of any use, as most of them flowered in late October—fully a month later than is desirable for outdoor displays in the United Kingdom. In the early nineties, however, this raiser sent out considerably more than one hundred Continental novelties in one year, and as far as the writer's memory serves him, not more than two trade specialists acquired the whole set. They were such a fine lot, however, that the collections of early-flowering Chrysanthemums throughout the country came to be enriched by their addition, and the aspect of the outdoor flower garden changed in a remarkable degree in consequence.

In 1894 plants of Mme. Marie Massé were first introduced, and so great a development did the introduction of this fine variety denote that it was grown by everybody, who at that time began to realise what a great advance it was upon any other variety then in commerce. It was the writer's good fortune to exhibit for the first time in this country flowers of Mme. Marie Massé, and to gain the first-class certificate of the National Chrysanthemum Society. At that period this variety was regarded as ideal, for it flowered most profusely, possessed an ideal branching habit, and its constitution was robust and vigorous. The rosy mauve colouring was appreciated at that period, as there was nothing in cultivation to equal it. In succeeding years this variety sported in quite remarkable manner, giving us in turn white, crimson (brunze crimson), cerise, yellow and a number of other intermediate tones of colour, each of which was highly valued as it came along. All these sports are still grown very largely. Once the stock was acquired, it was impossible to lose it, the constitution being so very excellent.

With the introduction of Mme. Marie Massé, English gardeners began to realise that they could save their own seed and raise seedlings of their own, and in consequence of this important fact succeeding years saw the introduction of many very beautiful sorts that completely eclipsed the results obtained by their Continental rivals. Pollen was so easily procurable from flowers of Mme. Marie Massé that numerous crosses were made, and for years it was possible to trace the parentage of the different new sorts to the variety already mentioned or to its progeny.

During the last decade English gardeners added many charming varieties to the lists of cultivated sorts, and of these, together with the introductions of M. Nonin, a French raiser of repute, there is now available for those who care to grow these plants a very lengthy list of early-flowering border Chrysanthemums that should satisfy the taste of the most fastidious. The flowers to which reference has been made in the foregoing notes are of Japanese form, and this has added very materially to the increased popularity of the subject. The old Pompons, beautiful in many respects when properly grown, are now seldom asked for, and this is a real pity, for they have a value peculiarly their own, being dwarf in most instances, and the plants are freely studded with dainty little button flowers that withstand the trying effects of rain as no other type of the flower is able to do. The Pompons look well when massed in beds by themselves, grouping the plants a colour in each bed, or associating those together that make a pleasing contrast. The Pompons never look better than when they are utilised as a groundwork in large beds, in which are planted at irregular intervals or in small groups disbudded

plants of such varieties as the yellow Soleil d'Octobre or its bronzy fawn sport, Bronze Soleil d'Octobre. In this method of planting I saw last season one of the prettiest displays of outdoor Chrysanthemums ever met with in this country. For this reason I would not discard the Pompons.

In later years the early-flowering single Chrysanthemums have come into being, and in a large measure they have revolutionised things. From the first they have been popular, and the quality, even of the earliest sorts, has been quite good. Needless to say, in their development the results have been marvellously good. The form of the flower has improved in a most marked degree,

the frosts cut the plants down. These plants will successfully resist the ill-effects of several degrees of frost. It is only when heavy rains fall persistently, and are succeeded by rather severe frost, that the double-flowered sorts begin to lose their beauty and succumb. And what plant can be expected to succeed in such circumstances? A matter for surprise is the fact that comparatively few professional gardeners appear to set a right value upon these plants, and yet they are capable of supplying the requirements of the house for quite a long period. In the comparatively few gardens wherein I have seen these plants grown extensively, those in charge of the gardens have always been loud in praise of them. The early-flowering Chrysanthemums are plants of the easiest culture, and only need quarters that are deeply dug and the soil nice and mellow. Except for staking and tying the plants, little else is required by them during the growing period. Covent Garden Market and other flower markets throughout the country have developed an enormous business since these plants have been improved, and it is by no means uncommon to meet with market-men who cultivate the early-flowering Chrysanthemums by the hundreds of thousands. The National Chrysanthemum Society holds its show of early sorts at the Crystal Palace on October 2 and 3 next. D. B. CRANE.

2.—A WEEPING STANDARD OF ROSE DOROTHY PERKINS IN THE BORDER AT PURLEY. THE BORDER IS EDGED WITH ALYSSUM MARITIMUM. (See page 488.)

and the flowers stand wind and weather so much better than the earlier series were able to do. The habit of growth varies. In some varieties it is fairly dwarf and bushy, and in others the habit is taller and more erect, evolving flowers on a good length of footstalk, so that individual blossoms can be used for decorations. As freely-flowered, undisbudded sprays these early-flowering single Chrysanthemums provide abundant material for indoor decorations.

It is their value in the outdoor garden, however, that growers have come to recognise. Amateur gardeners have for long taken full advantage of this subject, and, as a rule, their gardens have been a blaze of colour from late August onwards until

some flower-lovers who look upon the Dahlia as a very commonplace flower and as being quite unsuitable for decorative work of any description. But I should like to ask these people if they have ever tried the Dahlia as an effective bedding or border plant? Certainly a few of our large public parks and Kew are endeavouring to educate the world at large as to the value of this flower for colour effects, but only a tithe of the people see them, so progress is slow.

Again, I fear the majority of Dahlias are bought through seeing them at flower shows, and these are nearly always exhibition flowers that are rarely adapted for colour effect, and when planted the owner is disgusted because the only

DAHLIAS FOR COLOUR-SCHEMES.

I HAVE often wondered why lovers of garden colouring have avoided the Dahlia in their autumn colour-schemes. I can only suggest that it is prejudice on the part of most people, for one often hears the remark that they are such stiff, awkward flowers, and are only fit for florists and amateurs to exhibit at flower shows, while others will tell you that Dahlias are always suggestive of earwigs. Personally, I am under the impression that half the flower garden lovers have a very slight knowledge of the modern flower, for they only obtain their information by seeing a few odd plants in cottage gardens, or a few ancients that grow year after year on the borders of country railway stations, while there are

result produced is a mass of greenery. The plants can be had in flower by the middle of July onwards until the frost cuts them down. This in average years is usually the first week in November.

There is no autumn flower that can vie with the Dahlia for brilliancy. As a rule, all others appear dull in comparison. For massing we have scarlet, crimson, yellow, purple, orange, white and pink in self colours. These lend themselves readily to almost any garden colour-scheme if only the right varieties are grown, while they can be utilised almost anywhere, as they vary in height from 2 feet to 5 feet. Should the plants be required to flower in July or very early, the best plants for the purpose are old stools, which should be divided as small as possible, or perhaps better still, pot tubers, which are obtainable in the early spring months. These flower earlier than plants produced from cuttings, though the individual flowers are not so perfect, and, generally speaking, the double forms are liable to produce semi-double flowers, but for colour effect this is immaterial. Pæony-flowered Dahlias are very useful. The individual flowers

Garden Yellow is the best of its colour in this section, though Caradoc runs it very closely. In mauve shades Mauve Queen can be recommended. Perhaps the best crimson for our purpose is Conquest. This is very rich, with a splendid habit. The finest of the very dark forms is still the old variety J. H. Jackson. In bright crimsons Mary Purrier is quite the best. In cases where dwarf colour effects are desired, the bedding double varieties produce splendid masses of colour. They rarely exceed 2 feet high. Marguerite Bruant and White Bedder are both good whites. King of Dwarfs is a good purple. Flora Macdonald can be recommended as a fine yellow, while Rising Sun produces masses of scarlet flowers. The Pæony-flowered varieties have not been noted for their habit, because the flowers are so heavy. They have a tendency to hang down, but it is only a matter of time before we shall have varieties with excellent stems. At the present time a few of the best sorts are Bayard (red and yellow), Mrs. J. B. Riding (scarlet), Cecelia (yellow), Salome (buff apricot), Holman Hunt (crimson) and Mrs.

outskirts of the woodland there are few subjects that lend a more pleasing touch of colour in the autumn. Moreover, the Irish Heath is suitable for growing on rockwork or on sunny banks. It thrives in a sandy peat soil to which a little loam has been added. The name of this useful plant has so often been changed that a good deal of confusion still exists. Its Linnean appellation is *Erica Dabœcii*. In gardens it is sometimes met with under the name of *Menziesia*. *Boretta* is another name by which it is known, but most botanists and gardeners seem now agreed that its name is *Dabœcia polifolia*. It is a low-growing Heath, usually less than two feet in height, bearing drooping crimson-purple blooms considerably larger than those of the usual run of *Ericas*. The white variety seen in the foreground of the illustration is more showy than the type, and flowers with greater freedom. This Heath is found growing wild in Mayo and Connemara; hence its popular name of Irish Heath. Its natural distribution, however, is a little curious, since it also occurs in the Azores, a volcanic group of

islands in the Atlantic about one thousand miles from the coast of Portugal. However, this fine plant is perfectly hardy, and may be planted with confidence in any part of these isles so long as the soil is suitable for the cultivation of Heaths.

COLOURED PLATE.

PLATE 1455.

NEW WINTER-FLOWERING BEGONIAS.

A SPECIES that has played a very important part towards the production of the many winter-flowering Begonias of to-day is *Begonia socotrana*, which, valuable itself for its high ornamental qualities, is rendered ten times more so by reason of the importance of its numerous progeny. From the first it promised to be of considerable value to the hybridist, and was employed in various crosses.

The first result of this was the variety John Heal, named in honour of the raiser. It flowered in 1883, and was distributed two years later, when it was given a first-class certificate by the Royal Horticultural Society. This was obtained from *Begonia socotrana* fertilised with the pollen of a red-flowered tuberous-rooted variety, Viscountess Doneraile. Working more or less on the same lines, a great number of beautiful varieties were raised, and many of them are now extensively grown wherever flowering plants are in demand. Of the several kinds, the brilliant rose carmine coloured Mrs. Heal remained for a long time the best of the section. So matters stood until the autumn of last year, when, at the meeting of the Royal Horticultural Society on November 7, the veteran raiser, with a quiet confidence which betokened success, brought forward three new varieties, namely, Acquisition (bright pink, with a slight yellowish suffusion), Her Majesty (warm orange, with a reddish tinge towards the edges) and Exquisite (deep pink, with the edges of the petals darker, and a shading of orange, especially towards the centre). All three were obtained by the inter-crossing of *Begonia socotrana* and a yellow

DAHLIA KAISERIN AUGUSTA VICTORIA, A FREE-FLOWERING WHITE VARIETY FOR THE GARDEN.

may not be perfect in form, but as a mass of colour they are perfect. Even the double or show varieties produce wonderful colour effects when growing in masses. Where whole beds are devoted to them, only one variety should be grown in each bed, so that they are uniform in height and habit. Just a few of the best decorative kinds are: Kaiserin Augusta Victoria, not the Pæony-flowered variety, but a pure white decorative kind that grows about two feet to three feet high. This has been largely used at Kew and other places, and is always greatly admired. Pure pink is not often seen in the Dahlia, but we have it in the decorative variety Delice. This is a good sturdy grower that flowers on stiff stems well above the foliage. Massed in numbers the effect is perfectly charming. Scarlet is always admired, especially in the autumn months. Here we have the Cactus variety Amos Perry, which is still unsurpassed in its colour and habit; while the best white variety in this section is undoubtedly White Ensign, for it produces its white blossoms well above the foliage on fine stiff stems, which cannot be said of any other white Cactus I know.

T. G. Baker (white). The Pompons and many of the single varieties are equally suitable for massing, especially the self-coloured sorts, for most of them possess a fine sturdy habit. Those who contemplate utilising the Dahlia for this purpose should pay a visit to one of the nurseries where the Dahlia is a speciality. They could then make a selection for the purpose, for they could see the plants growing in quantity and so obtain the exact colours they need. R.

THE HEATH GARDEN.

THE IRISH HEATH IN AUTUMN.

SEPTEMBER is the month when the Irish Heath is seen in the height of perfection. Not that this is the only flowering season, for a continual display from May till October is usual, and this may be said of the bed illustrated on page 491, which at the time of writing (September 18) is flowering in the greatest profusion. For planting in large groups in the foreground of the shrubbery or on the

THE NEW WINTER-FLOWERING BEGONIA
FASCINATION.

ROSE MRS. CHARLES PEARSON. A NEW VARIETY OF INTENSE APRICOT-SALMON COLOUR. AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S AUTUMN SHOW.

flowered variety of the tuberous-rooted section, and the whole of them were given awards of merit by the floral committee. A fortnight later—that was, on November 21—the variety herewith illustrated, Fascination, was shown, and received a similar honour to the three already mentioned. The parents of this were *B. socotrana* and a copper-coloured tuberous-rooted variety. Another hybrid shown at the same time as Fascination was Rose Queen, whose large flowers are of a deep bright rose colour. It was obtained from *B. socotrana* and a white-flowered tuberous-rooted kind.

The main characteristics of these newer varieties of winter-flowering Begonias, compared with the older kinds, are a sturdier and more freely branching habit of growth, and larger and better-shaped flowers, which in general appearance suggest those of the tuberous-rooted forms. In foliage and in other particulars, but especially in the season of flowering, these varieties show markedly the influence of *Begonia socotrana*.

The cultural requirements of this class of Begonias are not at all exacting, provided a few important particulars are borne in mind. After the flowering season is over they should not be kept quite dry, as in the case of the tuberous-rooted varieties, for the *socotrana* hybrids do not form as solid a tuber as the others. Throughout the winter they should be placed in a structure where a temperature of 50° to 60° is maintained, and be kept fairly dry; that is to say, in a condition which the gardener would indicate by the expression, "on the dry side." With the return of spring the plants will soon begin to grow, and when the young shoots are long enough, they may be taken and inserted as cuttings. In a close propagating-case they will soon root, and when sufficiently

hardened off they may be potted singly or shifted into larger pots. Throughout the summer no fire-heat will be required, but a genial atmosphere must be maintained, and the structure in which the plants are growing be shaded from the rays of the sun. As the nights grow cold, of course, heat must be given in the pipes. The young plants, according to their vigour, will flower in pots from 4 inches to 5 inches in diameter, while a few of the strongest may be given even larger pots. If it is intended to grow the old plants on instead of propagating from them, they may, when the young shoots are from 1 inch to 2 inches in length, be shaken almost clear of the old soil and repotted. A suitable compost for these Begonias can be formed of two-thirds fibrous loam, pulled to pieces by the hand, and one-third leaf-mould, with a liberal sprinkling of silver sand. It may be noted

that the exceedingly popular *socotrana* hybrid, *Gloire de Lorraine*, was obtained by crossing the species just named and the fibrous-rooted *B. Dregel*.

THE FRUIT GARDEN.

THE BEST APPLES AND HOW TO GROW THEM.

(Continued from page 480.)

The Best Varieties.—The last question is that of varieties, and though this section must be headed *de gustibus*, I will try to cater for various tastes. First let us take dessert sorts, and I assume here that flavour is naturally the first consideration. The earliest Apple of first-class quality is no doubt

Irish Peach, perhaps a little shy in cropping, but so good as to merit a place in every collection. Following shortly after comes Williams' favourite (no relation of Williams of Pear fame, but a visitor from across the Atlantic). This Apple has not yet received the attention it deserves. Then, Lady Sudeley, a joy both for eye and palate; but, and this is an important "but," do not allow it to fully ripen on the tree. Gather and allow the Apples to come on in the fruit-room, or you will find them all ripe at one time. After this I recommend James Grieve, which at its best is unequalled in its season, and it will run close the best of any season. A good grower, cropper, and of handsome appearance, it will, for an all-round Apple, be very hard to beat. An excellent new-comer of about the same season is Hitchin Pippin, resembling Kerry Pippin in texture and flavour, but larger. I now come to the months of October and November—*embarras des richesses!* Mother, the American variety, is one that should not be omitted. Its fine flavour will appeal to all, and its soft flesh especially to those who are of riper years. [Does it crop well, everywhere?—Ed.] Margil, too, an old favourite containing the Ribston and Cox flavour, must be included. It makes a neat pyramid and crops regularly, though perhaps not so abundantly as could be desired, but it is distinctly an epicure's fruit. Allington Pippin needs no introduction, it having made its way into the front rank in the sixteen years of its commercial existence. If Cox's refuses to grow, try Allington.

The latter end of October sees the Reinette types of Apples come in. King of the Pippins, given a warm soil, is most desirable; a little tang of tannin flavour gives it a character of its own. Cox's Orange Pippin renders the month of November notable, and needs no adjectives; but perhaps a plea on its behalf may be entered. Do not gather too early. This applies also most especially to all the Apples of the Reinette class, such as the Russets, Blenheim Orange and Ribston. If gathered before quite "finished," they will acquire a rubber-like texture that will disconcert the most hardy of digestions. Ribston Pippin is another fruit we approach with some veneration, and,

AN EFFECTIVE GROUPING OF THE WHITE IRISH HEATH, A BEAUTIFUL DWARF SHRUB FOR AUTUMN EFFECT. (See page 490.)

rumour notwithstanding, it still grows and thrives. I have seen this year the finest fruit that has come my way. Warm soil and plenty of water, in my opinion, are the two principal needs of this delicious fruit.

December still sees Cox's in full sway, but the new William Crump is most promising, and should have a fair trial. Adam's Pearmain, for those who like a crisp Apple, is most delicious, and I confess my hand strays most often to its shelf at Christmas-time. And here also I would recommend an Apple which from its appearance would be consigned kitchenwards. Large, and of rather ugly Rambour shape, its dull green and brown skin gives little promise of its superb—yes, superb—flavour. Its name is Roundway Magnum Bonum. As the days grow longer, the various Russets come into season, and with the Crocus come Sturmer Pippin, Allen's Everlasting and Duke of Devonshire, all excellent if properly gathered and stored.

authority. Bramley's Seedling is also a good cooker when not too ripe, but more suited for standard growth than for dwarf trees.

January and February are the months of Lane's Prince Albert, an ideal garden Apple; and of the novelties, Edward VII. is very promising at this season. The absence of Wellington in the list is conspicuous, but the are as where it thrives now are so few and its successful years still fewer that I hesitate to recommend it; nevertheless, it is the best of all winter cookers in my estimation. Those having gardens on a warm, deep loam or brick earth will not want anything better; but it must be always sprayed and carefully pruned as precautions against the black scab, its special enemy, or the tree will go from bad to worse.

This list will, I am sure, shock nearly every one of your readers by its glaring omissions of their favourite sorts; but, after all, one can do no more than suggest. The reader himself must know by

Vacant Land.—As land is cleared of the remnants of crops it is excellent practice to put the digging or bastard-trenching—the latter, of course, for preference—in hand as soon as possible. It is the custom of some cultivators to leave all work of this nature until the end of October or November; but this is not wise, because the task is laborious and slow, and when one is forced to rush it along owing to unfavourable weather or other causes it is apt to be scamped, and the evil of this will be clearly apparent in the crops next season. Therefore bring it forward steadily as opportunity offers, never being satisfied with anything less than moving the soil to its utmost depth, as this is beneficial to the plants and economical of manure. Full trenching, in which process the positions of the surface and subsoils are reversed, is not recommended unless the cultivator is thoroughly familiar with the methods of soil working that have been adopted in previous seasons. It is desirable that the surface shall be left rough for the free admission of water, fresh air, and later on, let us hope, of frost.

Liming Ground.—Years ago far more lime was used on the land than is the custom at present, and in the majority of instances this is to be deplored. It is usual to rely more particularly on natural manures for the enrichment of soil in which vegetables are to be grown, and, when this is the case, at least once in five years, and sometimes even more frequently, a heavy application of lime ought to be given, because it improves the mechanical texture and at the same time sweetens and enhances the fertility of the soil. Ordinary lime is excellent, as also is ground lime; but perhaps ground limestone is the best of all where it is readily procurable. As a rule, it is wise to work in the lime after an interval of seven or eight days; but this need never be regarded as imperative, because the weather will invariably carry it down into the ground. After a heavy liming, such as is suggested for the purpose in view, it is excellent practice to rely almost exclusively on concentrated plant foods in the succeeding season, as they will keep the soil clean and, intelligently applied, will ensure splendid crops of all kinds. Where

METHOD OF LAYING A STONE PATHWAY. (See opposite page.)

Cooking Varieties now claim attention, and first of all comes Early Victoria, the best of the Codlin race. Fit to cook in August or the end of July, its even shape and regular cropping habits make it *facile princeps*. It cooks to a froth, and is of very white colour. To succeed, Ecklinville, where it thrives, is unequalled; but, alas! it is not what it used to be, and Grenadier is taking its place. The new Rev. W. Wilks will make a strong bid for the September and October season, and should certainly have fair trial. For November, Lord Derby is the staple market variety, but its cooking powers do not appeal to me, as it is rather brown, woody and tasteless. The newer Norfolk Beauty is making a strong bid for favour at this time, and has cropped well the last two seasons. Its parentage from Waltham Abbey has given it excellent cooking qualities. A word in favour of the old Beauty of Kent must be registered. Friends of mine say there is no cooking Apple so good, and I acknowledge their gastronomic

experience what he can and cannot grow, and in his hand must the final selection always rest.

Maidstone.

E. A. BUNYARD.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Lifting Beet.—With the advent of frosts it will be necessary to harvest the Beet, this being the most tender of the popular and valuable tap-rooted crops grown in gardens. It is not desirable to lift the roots until the leaves have been flattened down by frosts, but these must not be of sufficient severity to injure the root in the slightest degree. In storage each must proceed on the lines most convenient to himself; but heaps of alternate layers of roots and sand or fine, dry soil in a cellar or cool shed are admirable.

vegetables demand rotten manure in the trenches, such, for instance, as Celery and Leeks for exhibition, the case is slightly altered; but, apart from these exceptions, the artificials will respond to all demands.

Mustard and Cress.—It is a necessity of most gardens that there shall be an absolutely unbroken supply of these piquant salad plants at command, and, fortunately, it is never difficult to ensure it. Seeds can be sown on damp flannel, blotting paper or other material in dishes if it is desired, or the customary system of sowing thickly on the surface of soil in boxes may be adhered to, according to fancy or convenience. The important point to keep in mind is to sow at frequent intervals, and invariably to allow the Cress from thirty-six hours to forty-eight hours longer to come into use than the Mustard, as the seeds do not germinate as quickly and the progress of the plants is a little slower. Although some growers cover the seeds with soil, the practice is deprecated. H. J.

GARDENING FOR BEGINNERS.

STONE PATHWAYS IN THE ROCK GARDEN.

Most of us who are rock garden enthusiasts appreciate the peculiar suitability of a rough

in this way, so as to make them more presentable, and from the photograph on this page a fair idea

STONE FOR A PATHWAY. A INDICATES UNPREPARED STONE, B C AND D PREPARED STONE, AND E A LARGE STONE MADE FROM THREE PIECES.

antique stone paving for the paths which wander in and near the alpine garden.

While it is desirable that the finished appearance of such a pathway should be as irregular and careless-looking as possible, it by no means follows that the path can be satisfactorily made by just throwing down a number of uneven-shaped pieces of stone and filling in the spaces with soil; indeed, for the path to be a permanent success, considerable care should be taken with it in the first instance. It is another of the instances—which are so plentiful in the rock garden—of the art that conceals itself.

The Best Material.—Doubtless the most pleasing results would be obtained by employing slabs of softly-tinted sand or lime stone, just as they come irregularly-shaped from the quarries—frequently of a delightfully roughened surface. In my own case, however, the obtaining of such was out of the question, and the best I could do was to get from the local builder a load or two of waste oddments from some York paving. These pieces were mostly triangular, more or less regularly worked and smooth, while few were more than 15 inches on the longest side.

Preparing the Stone.—The first thing I did was to lay out and sort up into sizes the stones I had, and from among the largest I selected those which, when laid side by side in pairs, made up a fair-sized slab. These pairs were then taken and the outside edges chipped by means of a cold chisel, so as to take off the regular outline and give them an aged and worn appearance, leaving untouched, of course, the two edges which were to be joined together. All the pieces of stone were treated

can be obtained of the immense difference which it produced in their appearance. Fig. A represents the untouched stone, while B shows it after the edges had been worked. D gives a good idea of one of the selected pairs ready for laying, while E shows a large stone made up of three pieces, though the actual cementing of the joints was not done (except in this case, for illustrative purposes) until after they were in position. C shows one of the corners from a larger and exactly triangular stone (which had been removed to improve the shape of the latter) chipped so as to become a very useful item in the pavement.

Preparing the Soil.—The next point was to prepare the ground which was to be paved. In my case this had been a path with a gravelled surface. I dug out the whole to the depth of about six inches, and, after well consolidating it, put in 2 inches of ash, so as to make sure no worms would come through and worry the plants. Upon this I put 2 inches of soil composed of loam, sand and broken brick, in about equal proportions, with a little leaf-soil added. This I carefully levelled from side to side of the path, so that, while it sloped a little from one end to the other, the surface of it was smooth and the incline regular. When this was all firmly rammed, the pieces of paving-stone were placed upon it and so arranged as to give at intervals of about one step, though not in alignment, one of the larger “made-up” stones, which would receive the bulk of the tread, making the whole look much more pleasing than if the stones were all of a uniform size. Each of the stones was carefully and solidly placed, pains being taken to see that the surface of them all were in the same plane. This was much simplified by the use of a straight-edged piece of wood, as shown in the illustration here given.

Making Large Stones.—When this was done to my satisfaction, I allowed it to stand for a week, by which time the rains had settled the whole well together. I then mixed up some neat cement into a fairly liquid consistency and poured it carefully into the joints of the “made-up” stones, which joints, by the way, I had kept open when laying them by placing one or two fragments of grit so that my trowel would readily go in between them and pack the cement tightly—not merely surfacing the crack with a little cement and so getting no real hold. The illustration below also shows the path when completed and the edge of the rockery rising therefrom. REGINALD A. MALBY.

THE PATHWAY COMPLETED AND PARTIALLY FURNISHED WITH LOW-GROWING ALPINES.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Treatment of Bedding Plants.—There are many subjects utilised in the arrangement of formal bedding that will be required again the next season; for instance, standard plants of Fuchsias, Lantanas and Swainsonas. In order to keep them through the winter, a frost-proof structure should be found for them. We stand them in a deep pit where slight heat can be given when necessary.

Border Carnations.—The rooted layers will by now be ready for severing from the parent plants, whether they are to be potted up or planted out in the positions where they are to flower next summer. On wet, cold soils such as we experience here it will be necessary to add plenty of opening material, such as crushed brick or mortar rubbish and road drift. It is also a capital plan to plant in narrow beds raised slightly above the natural level and with an alley or a path between. Well dig the ground, adding some decayed manure as well as the other material, and leave it upturned for a day or two to settle the soil and expose any insects to the birds. Plant in lines, allowing 6 inches to a foot between the plants and a foot between the rows. Place some sharp cinder-ashes round each plant.

Lawns.—These will require frequent brushings to disperse the worm-casts, afterwards rolling, which will add considerably to their appearance and promote the growth of the grass.

The Rock Garden.

Planting.—If it is necessary to plant, especially the more robust of the occupants of the rock garden during the autumn, this may be done with the same assurance of their well-doing as in the spring, especially when transferred from pots, as the majority of them are now to be had established in that way. For instance, with the formation of new rock gardens or additions, it need not be postponed any later, and the plants will become firmly established by spring.

Top-dressing.—This ought not to be delayed any longer if the work has been overlooked. In many cases the frequent rains have washed much of the rooting medium away, especially on shallow and otherwise exposed positions. Work the material between the growths, and settle down by a damping over with a fine-rosed can.

Plants Under Glass.

Chrysanthemums.—These, and especially where grown for large blooms, more so than the decorative varieties, must be housed when there is likely to be a few degrees of frost, otherwise the buds will suffer. Elevate the plants as near to the glass as possible, so that the growth will not become drawn. Before housing, the foliage may be syringed with an emulsion of paraffin, keeping it clear of the buds, which will check the rust from spreading and generally free the leaves of any insect pests. Admit abundance of air to the plants day and night, except when the weather is damp or foggy, when the side ventilators should not be used so freely. A slight heat in the pipes will considerably lessen the damping of the petals.

Housing Plants.—At this season there are many other subjects that will be much safer and better for greenhouse treatment, and, before housing, a thorough cleansing of the structure is advisable, both for appearance sake and the benefit of the plants. Many people clean the interior, but seldom the exterior. I would recommend that both be done, and especially the latter, frequently, in smoke-laden districts. The use of blinds and other shading material will not be needed now, except in a few instances. Thoroughly dry the blinds or other material before storing them, and wash off any mixtures, such as Summer Cloud or whitening, from the glass.

The Hardy Fruit Garden.

Nuts.—There has been a good crop of both Filbert and Cob Nuts this season, and many will want to know the best means of preserving them for use during the winter months. For a time, of course, they should be sent to the table with the husks attached, having first looked them through to see if there are any earwigs in hiding. A good plan for storing is to clean the Nuts from the husks and store by taking out a hole in the garden

sufficiently deep to admit of a drain-pipe. At the bottom place a piece of slate sufficiently large, stand the pipe on it and fill round the outside with soil to make quite firm. Fill up with Nuts, place another slate on the top and cover with soil. In this way they will keep for months.

Fruits Under Glass.

Figs.—The earliest-forced trees will now be fast maturing their foliage, and the trees should be gradually rested accordingly. Less water will be required at the roots, and syringing of the foliage should be carried out in bright weather, while any leaves remain, to check the increase of red spider. Gather up the leaves that fall and keep the borders clean. Mealy bug is a troublesome pest, and before the days get too short the insects should be looked for and killed by the use of a little methylated spirit and a camel's-hair brush. Cyaniding is the best means of extermination, but requires doing with great care owing to its poisonous properties.

The Kitchen Garden.

Turnips.—These have been of excellent quality this season, and the roots may, if wanted, be taken up before they get too old, and stored in sand or soil in a cool shed in the same way as Carrots. Keep the hoe at work among the growing plants, and single out as they become large enough.

Radishes.—Make a small sowing or two at intervals in a cold frame wherever there is room between other plants.

Carrots.—The main crop of Carrots should by this date have completed their growth and be ready for lifting and storing away for use during the winter. Fine soil or sand should be sprinkled in among them, storing only the best-shaped roots.

General Work.—The garden should be made as tidy as possible at this season, and as fast as the crops have finished yielding, such as Peas, Beans, Marrows, &c., the plants should be pulled up and burnt, or the haulm removed to the rubbish-heap to be used later for placing in the bottom of the trenches. Continue to plant out Cabbages on vacant ground, and see that the plants are protected from slugs by placing some cinder-ashes round each. Globe Artichokes that have been touched by frost should be cut down or otherwise made tidy. Hoe frequently and keep down weed growth. Keep the paths clean and rolled during showery weather.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating Violas.—This may be proceeded with at any time during the next three or four weeks, choosing slips from the centre of the plants, the old hollow flowering shoots being unsuitable. The cuttings are usually inserted in a prepared bed in a cold frame, but they do well enough in a sheltered position in the open.

Other Plants.—Gazania splendens, Antirrhinum from selected plants, Pentstemons, Lavender, Veronica Andersonii variegata, Anthemis tinctoria, Golden Privet and Calceolarias are others which should be propagated at the same time. Cutting-boxes are best where only a few dozen plants are wanted, but for large quantities prepared beds in frames are better. It is a mistake to let any of the cuttings get dry and wilted, therefore take care to keep them wet till they are inserted, and afterwards it will be easy to keep them from flagging.

Walks.—Where these have to be hoed to destroy weeds, this may be done for the last time, choosing a drying day for the operation and raking the gravel as the work proceeds. Grass usually has to be picked up on account of its taking root so easily. Probably, if edged at the same time, the sides of the walks will remain quite neat till next spring. Let nothing remain that may possibly be an eyesore, but clean everything as perfectly as possible.

Mowing.—Besides closely mowing the lawns for the last time this season, all the odd places that necessarily have to be cut with scythes and shears should also be closely trimmed. Usually grass does not grow much after this time, and if it becomes a little rough, frost shortens it in due time without killing any of it.

Roses.—Any wild shoots should have a final tying to keep them from being damaged by wind, and they also look better if kept in position and not swaying in every direction. A certain amount of pruning in the way of removal of worn-out growths from bush plants may be performed with advantage. Trim Sweet Briar hedges for the last time this year, and see that strong shoots of Banksian Roses are secured for the winter.

The Plant-Houses.

Carnations.—The earlier Perpetuals will now be well in flower, and should be regularly cut while still young, else they do not last long and will prove a drag on the plants. If any aphid has been observed, vaporise a few times at short intervals. Soot-water and weak solutions of cow-manure are valuable helps to keep the foliage a deep colour, and also to brighten the flowers. These are to be preferred to sulphate of ammonia or nitrate of soda, which in the end softens the plants and hinders the production of bloom. Give all the fresh air possible.

Malmisons.—Any young plants still in frames should be transferred to a heated structure forthwith, and provision should be made to repot those at once that would do better with a shift before spring. Some cultivators, on the other hand, prefer to winter young plants in small pots, and no doubt there is less chance of ruining them by overwatering.

Arum Lilies.—Where the stock of these is planted out, the plants should now be lifted and placed in pots just large enough to contain the lightened balls, packing very rich material in to fill empty spaces. Let the plants stand in the open for a few weeks in a spot shaded from the sun. They do much better thus than if placed under glass immediately subsequent to being potted.

Schizanthus.—To succeed Cinerarias a sufficient number of plants should be placed in 4-inch pots, to be repotted as required later. The treatment as to temperature, &c., accorded to Carnations suits them perfectly, and though progress seems slow during winter, the plants grow very fast afterwards without being drawn and weak.

The Fruit Garden.

Late Peaches.—These will mature very slowly after this, and may require a slight heat in the piping during cold weather to hasten ripening. All superfluous growth should be rigorously suppressed, and unless the horders have been allowed to become dry, no more water need be applied at the root and syringing should cease. It is unusual for animated parasites to attack Peach trees after this date, but slight fumigations will be much better for the crop than syringing, should insects appear.

Maturing Wood.—It sometimes happens in a season such as the present that the young wood fails to ripen, when a fortnight's hard firing may be adopted, with a good deal of the old growths first excised. But much may be done by judicious winter pruning to counteract the evil of immature or partly immature growths.

Lifting Young Trees.—Any time during the next six weeks young fruit trees may be lifted with advantage, the over-long roots shortened and immediately replanted. The benefit of this operation is apparent for several years, but the intervals of relifting as above should not be too long extended. It is at once easier to operate in this way and better for the trees than to root-prune without lifting.

The Vegetable Garden.

Cultivating.—As opportunity permits, the cultivating of the garden by means of digging and trenching should be proceeded with. Many delay till it is possible to wheel on manure, but this is of secondary importance, soil broken up before winter sets in being much better than that cultivated later. In trenching do not be afraid to turn the top spit into the bottom nor bring the under spit to the top. The vicissitudes of the weather, wind, frost and rain, with manure, will put it all right before cropping-time.

Rhubarb.—Make preparation for the forcing of a quantity of this important winter vegetable. Select the strongest plants, which it is usual to let lie on the surface to check them sufficiently before placing in a warm structure or Mushroom-house. If lifted with soil attached, keeping the balls constantly moist by syringing, this is sufficient to keep them producing.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

SWEET PEA NOTES.

Autumn Sowing.—I am not sure whether it would not be just as well to alter this somewhat stereotyped headline to read "Autumn Buying." If the reports to hand from North, South, East and West are all quite true, there will be no Sweet Pea seeds left at the beginning of January, and it is, therefore, imperative that those who wish to have a few rows or clumps in their gardens during the summer of 1913 shall buy the seeds in the autumn of this year, even if they do not sow them then. I have some lingering impression in my mind that those who want seeds in the spring will be able to purchase them; but that the crops are short the world over none can possibly doubt, and it will assuredly be wise to order early in case of accidents. There is one advantage that will accrue upon the shortage of supply. In recent years seedsmen have given so many seeds in a packet that they have often been sown *à la* Mustard and Cress, and the growers have promptly condemned the seeds, the seed merchants and the plants themselves because perfect exhibition blooms were not produced. With a smaller number of seeds to sow, much more care will be exercised in carrying out every detail, and the ultimate result will be that Sweet Peas will be finer than they have ever been before, provided, of course, that the season is reasonably favourable to their growth. In any case, send for lists and despatch the order instantly.

Outdoor Sowing.—One must feel some regret that mice and slugs have a partiality either for the seeds or the seedlings of Sweet Peas, and thousands of plants are annually ruined by their depredations. Measures are taken to prevent serious injury every year, but the furred and feathered visitors are not easily denied, and it is rare indeed that they do not secure a fair share of the good things in the garden. However, the ardent grower will accept the risk in the hope that the plants which escape will produce superb blossoms that will win a few prizes and trophies at various shows. In a soil that is on the strong side, the present is an excellent time to sow; in good loams about the third week of October will answer best; while in warm sands the middle of November may usually be accepted as ideal.

It is obvious that the precise date of sowing will in each instance be governed by the weather. It is much wiser to wait a week or two than to sow in land when the conditions are not suitable. In any event, the trenches should be flat-bottomed and firm over soil which has been deeply and thoroughly worked and generously but judiciously manured. The depth of covering will depend largely on the consistency of the soil, and, in a smaller degree, upon the variety in hand. In a sandy soil seeds may be set deeper than in a clay soil, and the light-coloured and spotted seeds ought not to be more than pressed into the surface.

Indoor Sowing.—The majority of people who aspire to the production of exhibition Sweet Peas and pin their faith on autumn sowing adopt the system of putting the seeds in pots in cold frames, and there can be little, if any, doubt that the practice is wise. Six-inch pots, filled to within about one inch of the rim, with a compost of three parts loam, one part refuse manure and an eighth or a tenth part of sand, are most favourable, though 3-inch pots may be utilised under compulsion. In the larger size five seeds will be set equidistantly 1 inch from the sides, while in the small pot one seed will find accommodation in the middle.

The secret of success in autumn sowing in pots lies in growing from the start in the hardiest possible manner. Even the slightest suspicion of coddling will be followed by worry and trouble, if not by disaster. Broadly speaking, the tenth day of next month is the best time to sow in pots, but in this matter there will be slight variations, governed by the experience of each cultivator in his individual surroundings and circumstances. Although it cannot be written down as necessary, the wisdom of sowing the light-coloured and spotted seeds in a surfacing of sand over light, porous soil cannot be questioned. HORACE J. WRIGHT.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

AURICULAS (*Zedox*).—One cannot recommend any particular varieties for cross-fertilisation. You must use those possessing some special feature of colour, size, form, or substance which you especially desire to improve. We do not know any book devoted exclusively to the Auricula. There is no objection whatever to the use of burnt ballast for the purpose named, and we wish you every success.

SWEET PEAS (*W. H. Cox*).—The leaves of the Sweet Peas are really grand, but some of the flower-stems are extremely weak. The plants have either received a check or the roots are working in some unsatisfactory medium. It is more than probable that if you had kept the laterals well pinched out, watered and mulched the plants to keep them in steady progress, you would have experienced no further serious trouble.

DELPHINIUM DISEASED (*E. B., Handley*).—The leaves are affected by the fungus known as Septoria delphinella, and we can only suggest that you at once cut down the plants to the ground and burn every vestige of leaf and stem. In this way, unless the fungus has already matured, it may be possible to keep it at bay. Should there be in the new autumn growth further evidences of the disease, cut off the affected parts and burn them at once. Hitherto we have been spared the infliction of this disease, though in the past year or two it has appeared in more than one collection of these plants. As a precautionary measure, another year you might early spray the plants with permanganate of potash, or a weak solution (1oz. to the gallon of water) of sulphide of potassium.

ROSE-BEDS AND TULIPS OR DAFFODILS (*E. M. M.*).—Considering (1) the exposed, windy situation, (2) the heavy soil, and (3) that it is wished to leave the bulbs in the bed for two or three years, we do not advise Tulips, but Daffodils. If, however, it is decided to try Tulips for one year or so, we strongly advise their being lifted as soon as the foliage has become yellow. In a lighter soil they might be left undisturbed. For April blooming they must be early-flowering varieties, and we would advise one colour only in each bed. Vermilion Brilliant (red) and Erubilde (white with yellow flame) would be a good combination; Yellow Prince (dwarfish yellow) and Prince of Austria (terra-cotta, tall) would be another; while as a third choice, a decided novelty, we would suggest Hector (orange red, edged pale yellow) and Primrose Queen (primrose yellow). If four varieties of Tulips are essential, Fred Moore (orange), Prince de Ligoy (rich yellow), Prince of Austria (terra-cotta) and President Lincoln (rosy purple) are the ones suggested, or the last two of the above pair combinations might be used together. Should Daffodils be decided upon, the choice is very wide. One variety to one bed should be the rule; everything looks its best in a mass. Emperor and Empress in alternate beds is one suggestion; Autoerat, Mrs. Langtry, Beauty and Constellation another. These are all cupped sorts. Aspasia, Elvira, Irene and Klondyke would make four good Poetaz varieties. If bold trumpets are desired, Mme. Plomp, Glory of Leiden, Cornelia and Fairy would be a good quartet.

TO PROPAGATE PHLOXES (*R. P.*).—Spring or autumn is the best time to propagate these. Select the young shoots at the base of the plant. These should be inserted in 6-inch pots (filled with sturdy soil) an inch apart, and the pots placed in a warm pit or frame, shaded from bright sunshine. As soon as the cuttings are rooted, let them be potted into 3-inch pots, wintered in a cold frame, and planted out at the end of March. They may also be propagated from seed.

TREATMENT OF ANNUALS AND OTHER PLANTS (*C. S. K.*).—We should not recommend pinching out the tops of Stocks or Wallflowers generally, since there are so many dwarf bushy and free-flowering types which branch naturally and quite low down, and if dwarfness and freedom of flowering are the main objects in view, you should grow these for preference. Legginess and spindly growth in such plants, however, are frequently created by inferior culture, by overcrowding of the seedlings, by long standing in the seed-bed and in other ways, and if your method of treatment has embraced any of these, you had better correct them. An over-shaded garden where there is much tree-life also brings this legginess into being. Seeds require to be thinly sown, to be early transplanted, and given elbow-room if all their good attributes are to be brought out. Verbenas are most usually stopped several times when used as bedding plants, pegged down, the object being to cover space, and this being accomplished, the plants are allowed to go. It is by no means essential, however, and we have seen seedling examples, when expertly grown, produce a 2-feet mat of growth in a season without a point being removed. The Nemesias require a rich, warm and moderately light soil, and unless attacked at the base of the stem by wireworm or millipede, should have made a favourable growth in a season like the present. In a cold or ill-drained soil these plants are not usually a success.

THE GREENHOUSE.

EXHIBITING AN ASPIDISTRA (*Chitraloe*).—There is no objection to the sticks used for supporting the leaves of Aspidistras; but it would be far better to remove them, as the leaf-stalks should be quite strong enough to do away with the need for sticks. In keen competition the sticks would be regarded as a demerit.

STATICE PROFUSA (*Mrs. Annesley*).—This species requires the protection of a greenhouse, though, if kept moderately dry at the root during the winter season, it would be quite safe in a temperature of 40° or thereabouts. You would be able to obtain plants through Messrs. James Veitch and Sons, Limited, Chelsea, S.W.

COBÆA SCANDENS (*A. W. J.*).—There is no sign of living insects on the leaves of *Cobæa scandens variegata* that you have sent. They must, however, have been very badly attacked by aphides or green fly, as one of the leaves sent on the under side is absolutely clothed with the excrement of these pests. This has, in its turn, afforded a ground for a fungus attack, which has destroyed the weaker portions of the leaves. If all the insects are dead, you can do nothing in the matter, as the leaves are of too delicate a nature to wash them with soft soap and water, which would be effective in the case of firm-textured leaves. Our opinion, however, is that the *Cobæa* being of good free growth, these leaves that are unable to fulfil their natural functions will soon drop off and new shoots be pushed out provided (and this is a most essential matter) that aphides are not again allowed to effect a lodgment on the plants. For the destruction of insect pests, vapourising with the XL All Vaporiser is much preferable to fumigation in any form.

FERNS (*W. E. P.*).—The name of the specimen sent is *Platyceerium Aleicoorne*, known popularly as the Elkhorn Fern. In a state of Nature it grows principally on trees in the forks of the branches, or on the stems, to which it attaches itself by means of its roots. As will be understood, this Fern is not seen at its best when grown in pots in the ordinary way, but succeeds when fastened to a piece of virgin cork, or the portion of a stem of a Tree Fern. It must, of course, have some rooting medium, consisting mainly of fibrous peat and live sphagnum moss, which may be kept in position by means of copper wire. It is, of course, necessary that the plant be regularly watered, and if hung up, which is the best position for it, a good way to supply its wants in this respect, provided it is not too large, is, when dry, to take it down and soak it in a pail of water. This Fern is a native of Australia, and during the winter months needs a temperature of 50° to 60°. In the summer no fire-heat will be needed. Of course, like Ferns in general, it must be shaded from the direct rays of the sun.

AZALEAS (*E. B.*).—Although it is now rather late, we should advise you to repot your Azaleas as soon as possible, as the new fibrous roots will soon take possession of the fresh soil. As they are now in 5-inch pots it will be as well to put them into 6-inch or 6½-inch ones. A suitable compost consists of fibrous peat with a little silver sand. In repotting, the crocks should be taken from the bottom of the ball of earth, and the outside of the entire ball be loosened with a pointed stick. The roots, however, must not be disturbed more than is necessary. When repotting it is very essential that the old ball of earth is in a fairly moist condition, while it is also of equal importance to see that the new soil is made very firm and even all round. For this a piece of wood, such as a portion of a lath, will be very useful. After being repotted it is very important to see that they are not allowed to get too dry at the roots, while an occasional syringing, especially on the evenings of hot days, will be of great service. Another point to bear in mind when repotting is that the plant must not be buried deeper in the soil than it was before.

ROSE GARDEN.

VARIOUS QUERIES (F. H. Hallfax).—The Rose we believe to be Reine André, one of the wehrhauana tribe. W. A. Richardson would be an excellent variety to grow under glass; but instead of Reine Marie Henriette we would recommend Climbing Liberty. Some other good climbers for cold greenhouse culture are Climbing Lady Ashdown, Gustave Regis, Bouquet d'Or, Hugh Jackson and Frau Karl Druschki.

ROSE BUDS INJURED (Fourwinds).—The usual cause of hard and malformed buds, such as those sent, is a check during development, such as might be imposed by cold nights, drying winds, or lack of rain. Some varieties appear to be more subject to it than others. The brownning of the foliage of the Plum sent is not due to any insect or fungus, but to something wrong with the water supply. If this is seen to, unless the roots have perished, there will probably be no repetition of the trouble next year.

ROSES FOR COOL GREENHOUSE (A.).—Some good climbing Roses for a cool greenhouse would be Bouquet d'Or, W. A. Richardson, Climbing Mr. Grant, Climbing Lady Ashdown and Grass an Teplitz. These could be grown on the roof, wall, or upright supports. The following bush or dwarf Roses would also provide plenty of bloom: Caroline Testout, Mme. Abel Chatenay, Mme. Ravary, Mrs. Aaron Ward, Antoine Rivoire, Anna Olivier, Mme. Hoste, Frau Karl Druschki, La France, Captain Christy, Captain Hayward, Ulrich Brunner, Richmond, Lady Pirrie and Augustine Guichonseau.

ROSE FOLIAGE BLIGHTED (J. M.).—We fear you can do nothing now for the black spot save gathering up the fallen leaves and burning them. Another year try spraying early with Cupram or Bordeaux mixture, and continue this at intervals throughout the season. If the Roses have not been too long in the present position, it would be well to transplant them in October. Just dig them up and heel them in in any out-of-the-way place, then have the soil trenched and the top soil for a few inches in depth buried in the bottom of the trench; then replant the Roses. They will do all the better for such a transplanting. Of course, you would leave out any sickly plants, for it does not pay to nurse up weak things.

ROSES SUDDENLY FAILING (Mrs. M.).—Probably the plants have suffered from drought, or maybe there has been an overdose of chemical manure used in the soil, or probably they have recently received some liquid manure that has proved too strong for the young roots. While either of these things may be the cause of failure, we cannot but think the plants have some disease which is peculiar to foreign-grown plants, for we notice by the labels that they are not English grown. We are confident that much of the black spot and other diseases frequently found to-day in our gardens are introduced upon these foreign plants, and we would advise you to procure your supplies from home growers who have a reputation to maintain. All you can do now is to make sure it is not drought the plants are suffering from, and if you think it is, give a good soaking of plain water.

INJURY TO ROSES (R. T.).—From the condition of the buds of your Dorothy Perkins Rose which were sent for examination, we should imagine that they are attacked by mildew. This may be easily ascertained, for in the event of the disease being present, the leaves, young wood and flowers would be covered, more or less thickly, or perhaps in patches, with a greyish powdery substance. If this is found, you had better spray the plant with Bordeaux mixture, taking care to damp both sides of the leaves. The mixture may be prepared as follows: Dissolve 1 lb. of copper sulphate in two quarts of warm water in a wooden vessel; then dissolve 1 lb. of quicklime in cold water to make a thick cream. When cold, mix the two together and make up to ten gallons with clear water. The mixture may be used now, but further applications must be made next spring when the leaf-buds are breaking into growth. Another effective fungicide may be made by dissolving 1 lb. of potassium sulphide in fifty gallons of water. This mixture should be used as recommended in the other case. Rhubarb clumps are weakened by being forced in successive years. We advise you to force the clumps in alternate years only. The leaf sent for determination appears to be a large-leaved form of *Ficus repens*.

FRUIT GARDEN.

GOOSEBERRIES SHRIVELLING (Miss E.).—The shrivelling of the Gooseberries is due to something interfering with the flow of water up the plant, not to any disease of the berries themselves; but what it is is not evident from the specimens sent. One must see the stems and foliage as well.

APPLE AND PEAR LEAVES FOR INSPECTION (J. H.).—The Apples and Pears are attacked by the Pear leaf-miner moth. It is difficult to deal with, the only practical method being to watch during May and June for the moths, which are very small and greyish in colour, and spray the trees then with lead arsenate. The moth lays her eggs on the leaves.

MADRESFIELD COURT GRAPES SPLITTING (M. G.).—The cause of splitting is too damp and close an atmosphere at this stage in the growth of Grapes. Splitting is a common complaint with the grand variety of Black Muscat. The danger time of splitting is when the Grapes are approaching full size and about to start colouring until the end of the time of colouring. The way to prevent splitting is to admit air freely at this time, day and night, through the front and top ventilators, and to prevent the temperature becoming too low, especially at night. Have a little fire-heat during the whole of this time. A gentle heat in the pipes dries the air and keeps it in constant circulation.

INJURY TO LOGANBERRIES (T. E. W.).—The maggots in the Loganberries are those of the beetle *Byturus tomentosus*. This pest also attacks Raspberries and Blackberries, and passes from the wild to cultivated plants. It lays its eggs in the flowers (on the pollen of which it feeds), and may readily be seen in them. Spraying with lead arsenate when the plants are in flower appears the best way of dealing with it.

INJURY TO PEARS (F. W.).—The Pears are attacked by the fungus *Fusicladium pyrinum*. Nothing can be done now to cure them; but next winter cut out all diseased wood, spray the trees with 1 lb. of copper sulphate to twenty-five gallons of water, and in the spring with Bordeaux mixture before the buds burst and again as soon as the petals fall, also about three weeks or a month afterwards. Burn affected fruits.

MISCELLANEOUS.

PARASITE (J. C. H.).—The worm sent is a species of *Gorhous*, which lives as a parasite for the greater part of its life in the intestines of an insect, such as the ground beetle which you enclose with it. The latter is a carnivorous insect, and therefore likely to be a useful one in the garden. Its larval form is also carnivorous. The Curran's which are infested with aphid should be sprayed with Quassia and soft soap. Some good may be done now, but more would have been done if the spraying had been carried out when the foliage was first attacked.

SOIL FOR INSPECTION (Northern Reader).—The soil is very poor stuff indeed, and we should advise you to have some new soil if you desire to grow good Roses. If you use any of this, you must add fully one-half of good turfy loam, for it is largely deficient in humus. You should also add one part out of three of good cow-manure. We advise taking out this soil 3 feet in depth, then add two parts of new soil from a meadow, or top soil such as you sometimes obtain where building operations are going on, one part of the soil you take out, and one part of cow-manure; then mix together and return to the beds.

DRESSING FOR LAWN (J. H.).—You will do quite right by giving your lawn a dressing of soil as you suggest, and then sowing seed where the grass is thin. The work ought to be taken in hand about the end of September, for at that time the ground is warm and the seed will soon germinate, thus giving the young grass plants time to get strong before winter sets in. Next year you may put sea sand over the lawn, taking care to rake it in well and roll it well. This will tend to encourage the finer grasses, and will be against the development of the coarser kinds. Subsequent dressings of sea sand may be necessary, while it would be good to thoroughly mix a fair quantity of bone-meal with it before applying it.

MOSS BALLS FOR EXAMINATION (M. A. B.).—The moss sent for examination was *Leucobryum glaucum*, a species which is frequently found in woods which are rather bare of vegetation. It possesses the peculiarity of growing in dense, ball-like tufts, which may be from 1 inch or 2 inches to 6 inches or more in diameter. These balls sometimes become detached from the surface upon which growth has originated, and the plants continue to live for a considerable period in this condition. The species is found in many parts of the country, notably in the Beech woods of Surrey, Sussex, Hertfordshire, &c. As a rule, it occurs in the damper parts of the woods, and might easily be mistaken for a compact form of sphagnum.

TO DESTROY ANTS (C. L. G.).—The recipes for the destruction of ants are numerous and varied; but there is not one so successful as flooding their nests with boiling water. It often happens that their nests are fixed in awkward places, such as among the roots of trees, where this remedy could not be applied. A good plan is to place a small ridge of fresh-slaked lime on the border round the trees, and not too far from them. This will prove an effective barrier to their getting to the trees. Boiled bones, partially cleared of meat, and sponges dipped in treacle form excellent traps for them. They should be placed under the tree or among the branches, and will soon be covered by the insects. They are then easily destroyed by steeping in boiling water. Either the bones or sponges may again be returned to their places under the trees to secure another lot.

NAME OF PLANT.—*M. M.*—The Orpine, *Sedum Telephium*, a native of Britain.

NAMES OF POTATOES.—*J. W. Hatchett.*—It is very difficult to name many sorts of Potatoes, but yours are distinct. They are: 1, Herd Laddie; 2, Edgemoor Purple; 3, Adirondack.

NAMES OF FRUIT.—*G. W. L. B.*—The Apple that you say is a seedling is King Harry, a second-rate dessert variety.—*Miss Johns.*—Both 1 and 2 are Wellington.—*A. I. Sampson.*—1, Marie Guise; 2, Louise Bonne de Jersey; 3, Thompson's; 4, Josephine de Malines; 5, Marie Louise d'Uccle; 6, Wellington; 7, Washington; 8, Fearn's Pippin; 9, Lord Derby; 10, Lord Suffield.—*E. A. Turner.*—1 and 5, Bramley's Seedling; 2, Round Winter Nonsuch; 3, Sandringham; 4, Striped Beaufin; 6, Lane's Prince Albert; 7, Gasconne's Scarlet.—*H. Salter.*—1, Warner's King; 2, Eckinville Seedling; 3, Dutch Mirabelle; 4, King of the Pippins; 5, Hall Door; 6, Wellington; 7, Catillac; 8, Beurre d'Arenberg (query, arrived rotten); 9, Darondeau.—*B. S.*—1, Marie Louise d'Uccle; 2, Beurre de Die; 3, Doyenné Rousseau; 4, Duchesse d'Angoulême; 5, Glou Morceau; 6, Wellington.—*A. G. S.*—1, Dutch Mirabelle; 2, King of the Pippins; 3, Lemon Pippin; 4, Warner's King; 5, Wellington.—*T. H. O. Pease.*—1, Cox's Pomona; 2 and 3, Lord Suffield; 4, Lady Hamilton.

SOCIETIES.

NATIONAL DAHLIA SOCIETY.

The annual exhibition of the National Dahlia Society was held at the Crystal Palace, Sydenham, S.E., on September 17 and 18. One of the chief features of this exhibition was the increased interest displayed in the Peony-flowered and the newer Collarette Dahlias. At the same time, the Cactus-flowered section were admirably represented, and the time-honoured show Dahlia, having lost none of its popularity as a garden flower, was also shown well. Some very attractive exhibits of singles and Pompons were to be seen, and much interest was shown in the novelty Crawley Star, the forerunner of a new race henceforth to be known as Cosmea-flowered. A description of this new break appeared in our issue last week, page 480. Of the Collarette Dahlias shown, none attracted more attention than Maurice Rivoire, one of the earliest varieties of this new departure. Other good varieties of the same section that were freely shown were Bismarck, Meteor and Henri Farman. Four of the best Peony-flowered varieties, all of which were well shown, were The Geisha, South Pole, Hampton Court and Liberty.

NURSERYMEN'S CLASSES.

The nurserymen's classes were in most cases well contested, and blooms of first-rate quality were noted, particularly among the Cactus-flowered section.

Messrs. Stredwick and Son, Silverhill Park, St. Leonards, gained the silver challenge cup for Cactus Dahlias with blooms of the finest quality. The same exhibitors carried off a gold medal for the best seedling Cactus Dahlia, Gigantea, a bronze red variety of remarkable size.

Mr. M. V. Seale, Sevenoaks, showed capital blooms of Cactus Dahlias, and was well to the fore among competitors.

Messrs. Cheal and Sons, Crawley, were particularly successful with fancy singles, and their novelty Crawley Star, to which we have already referred, came in for a deal of attention.

Messrs. Keynes, Williams and Co., Salisbury, gained the premier award in the large class for forty-eight Cactus-flowered blooms, distinct. It was an admirable collection and in every way a credit to the exhibitors.

Mr. S. Mortimer, Farnham, was once again to the fore with show Dahlias, and was a capital first for forty-eight blooms, distinct, and again for eighteen blooms, distinct.

Messrs. J. Burrell and Co., Cambridge, were prominent with Pompon Cactus blooms; and Mr. Charles Tamer, Slough, was well to the fore in the classes for Collarette and Peony-flowered Dahlias.

Messrs. William Treseder, Limited, Cardiff, were easily first for a basket of Dahlia blooms, showing an immense basket of crimson and yellow Cactus-flowered varieties with ornamental foliage. The same exhibitors were first for twenty-four Cactus-flowered Dahlias, distinct varieties.

AMATEURS' CLASSES.

Competition in these classes was generally very good and the quality, particularly among the Cactus blooms, was quite as good as could be expected in a season not favourable to Dahlia culture.

Mr. H. Peerman, Glenocross, Nantwich, gained the premier award and silver medal for twenty-four blooms, distinct, with a fine and uniform set of Cactus-flowered varieties. Among the best blooms were Glory of Wilts, Ivernia, Johannesburg and Olympia.

Mr. S. H. Cooper, The Hamlet, Chippenham, Wilts, was the winner of a silver challenge cup for twenty-four fancy blooms with a capital selection, among which we observed Pleasant, J. T. Saltmarsh and T. Jones.

Mr. F. W. Fellowes, The Lane House, King's Walden, Hitchin, won the society's silver challenge cup for nine Cactus-flowered varieties, three blooms of each. It was a fine and attractive stand. His blooms of Ivernia, Mrs. Stredwick and Glory of Wilts were perhaps the best of a very fine lot.

Mr. Luckin Apsley, Thakeham, Pulborough, Sussex, was a very successful exhibitor, his first-prize blooms of fancy or intermixed Dahlias being greatly admired.

Mr. H. Brown, Dahlia Dene, Sutton, won the silver challenge bowl for Pompon Dahlias in keen competition. Among the best blooms were Violet, Nerissa and Jessica.

The silver challenge cup for garden Cactus Dahlias was won by the Rev. Arthur Bridge, Worth Rectory, Three Bridges, Sussex, for effective and well-arranged vases of blooms.

TRADE GROUPS.

Large Gold Medals.—Messrs. Cammell and Sons, Swanley, Kent, for a representative collection of Dahlias; and Messrs. Spooner and Sons, Hounslow, for a magnificent collection of Apples, comprising 150 varieties, also Pears, Bullaces and Crabs.

Gold Medals.—Mr. J. B. Riding, Chingford, Essex, for a group of Dahlias, including Collarette, Peony-flowered and Anemone-flowered sections; and Mr. J. F. West, Tower Hill, Brentwood, for Dahlias of all classes, among which the Pompons were a strong feature.

Large Silver-gilt Medals.—Messrs. Ware, Limited, Feltham, Middlesex, for Dahlias, Begonias and herbaceous plants; and Messrs. Carter and Co., Raynes Park, London, for Dahlias tastefully arranged with Ferns in a circular group.

Silver-gilt Medals.—Messrs. Hobbies, Limited, Norfolk Nurseries, Dereham, for an extensive collection of Dahlias, in which the Collarettes were well represented; and Mr. J. Emberson Walthamstow for a general collection of Dahlias.

THE GARDEN.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

A Simple Autumn Border.—A simple yet effective border that we noticed in a small garden a few days ago is worth recording. This was planted with a double row of the yellow-flowered *Chrysanthemum Horace Martin* at the back, with a single row of *Goacher's Crimson* in the foreground, the whole being finished with a foot-wide edging of *Alyssum maritimum*. Although certain shades of yellow and crimson do not harmonise well, the effect produced in this instance was most pleasing.

Begonia Froebelii incomparabilis.—Those who remember or have grown the original type of this *Begonia* will find the variety named a decided improvement, as much in the richness and intensity of the colour of the flowers as in their size. A characteristic of the section is the rather woolly, spreading and nearly prostrate leaf-tuft, above which the flower-stems rise to 9 inches or so high. The flowers are of an intense crimson, the buds, like the footstalks, being covered with a soft white tomentum.

The Azalea Garden in Autumn.—Hardy Azaleas are so very pleasing in late spring and early summer when smothered in blossoms varying from palest pink to deep orange that we are apt to overlook the value of these shrubs for their autumnal tints. At the present time the foliage of the Ghent Azalea or Swamp Honeysuckle is in varying hues of bronze, purple and crimson. The Californian species, *A. (Rhododendron) occidentale*, is one of the best in autumn, and others that may be noted for their autumn tints are flavum, flavum tricolor and sinense.

Rudbeckia laciniata.—This showy Cone-flower has been very good this season, the wet weather apparently suiting it better than that of last summer. This is not surprising, as it is a native of moist thickets in the Northern United States. Growing to 6 feet, 7 feet, or even 8 feet in height, it is showy with its deep yellow, green-centred flowers, which are useful for cutting. For the back of the border or for the wild garden it is an excellent subject, while the long continuance of bloom, which is one of its characteristics, renders it valuable for the small garden as well as for the large one.

Perennial Asters as Woodland Flowers.—The value of perennial Asters or Michaelmas Daisies for colour effect in the woodland should be far more widely known than it is. At Kew the woodland garden is made to look very attractive at this season by the large informal groups of perennial Asters scattered about in various parts of the grounds and under the shade of trees. The Italian Starwort (*A. Amellus bessarabicus*) is admirably suited for woodland planting. Robert Parker is another variety that is amenable to this mode of culture, and others that are robust and free-flowering

may be relied upon for pleasing touches of colour in the woodland at this season.

A Rock Garden Near the Strand.—As evidence of the intense interest that is now being taken in rock gardening, it is worth recording that an alpine garden is about to be built in the heart of London and only a few yards from the busy Strand. At the north end of Waterloo Bridge, and opposite Somerset House, an open space has for some years been occupied by Bay and other trees in tubs, these belonging to Mr. Buder, a florist of Wellington Street. In association with these trees Mr. Buder is about to make a rock garden, and we understand that the Porthywaen Lime Company, Limited, Oswestry, are supplying the stone, which is Welsh mountain limestone. It will be of considerable interest to note which plants thrive in an atmosphere that is far from ideal for the bulk of alpine subjects.

Our Special Rose Number.—Now that the season for planting Roses will soon be with us, a great many of our readers will require information respecting the best Roses for various purposes. Our next issue will therefore be mainly devoted to the Queen of Flowers, and we think it will be the best and most interesting Rose Number ever published. Among those who are contributing are the Rev. J. H. Pemberton (president of the National Rose Society), Mr. George Laing Paul, Miss Jekyll (who gives a plan of a Rose garden with the Roses arranged according to their colours), Miss Langton (who writes on the best Roses for table decoration) and Mr. H. E. Molyneux, while our regular contributor "Danecroft" will give some particularly useful information about the best Roses for bedding. This issue will be considerably enlarged and beautifully illustrated, and a coloured plate of Rose Duchess of Wellington will be included. The price will, as usual, be one penny.

The American Smoke Tree.—The value of this tree in our gardens is largely confined to its autumn beauty, and it is more than worth growing for the gorgeous tints assumed at this season. Among the many trees and shrubs which are now fast assuming or have taken on their autumn colour at Kew, the glowing foliage of the American Smoke Tree, or Chittam Wood (*Rhus cotinoides*), is particularly noticeable. The best examples are three tall bushes in a bed near the Victoria Gate. So vivid or glowing are the rich orange scarlet leaves that they might, with the sun shining on them, be almost described as fire-like. Inspection of the many other beautiful shrubs and trees in their autumn garb does not reveal anything quite like the glow in the leaves of this *Rhus*. Experience in its cultivation seems to show that the colouring is better when the shrubs are planted in light, sandy soil without the addition of manure or rich turfy loam.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose General Macarthur.—I think a likely explanation of this splendid dark Rose failing in some gardens and taking mildew in others, as mentioned on page 446, issue September 7, may be that they are budded on the Manetti stock. I have a long row on the Briar, and they are quite free from mildew and blooming gloriously now (September 23). We have quite discarded the Manetti as a stock, in justice to buyers.—GEORGE BUNYARD, *Maidstone*.

Crinum Powellii.—I should like to confirm all that has been said in praise of the above plant on page 475, issue September 21, and would add a further word on behalf of its noble foliage. Arching over from the centre of the plant, the clean, shiny leaves give it a handsome appearance, especially with several off-growths coming up around the parent bulb as they have done with us. A few of our longest leaves are 5 feet in length. For protection in winter a covering of ashes is placed over it as the foliage dies away.—C. T. *Higgate*.

Crimson Hybrid Tea Roses.—In reply to "Rubrum," page 474, issue September 21, I find the best, and to many the least known, crimson Hybrid Tea Rose is Château de Clos Vougeot. It has flowered in Yorkshire throughout the whole of this sunless summer, and never loses its colour as do the other crimson Roses. It is also deliciously fragrant.—B. K. G., *Yorkshire*. [We agree with our correspondent respecting the colour and fragrance of this Rose. During the scorching days of last year it was the only crimson variety that did not lose its colour with us. Its ungainly habit, however, is a serious drawback for bedding purposes.—ED.]

Hollyhocks.—Early October is a good time to plant Hollyhocks, and they are seen to the best advantage planted at the back of the herbaceous border, on the outskirts of the shrubbery, or a dozen planted together to form a conspicuous group in some corner. They do best in a good, rich, deep, well-manned soil. The noble spikes of rosette-like blooms in such varied colours are very effective from July until long after the autumn frosts. Disease is prevalent among Hollyhocks, more so in some districts than others. One good preventive is one pint of slaked lime, one pint of soot and 1oz. of flowers of sulphur, well mixed together and dusted over the plant, three or four times during the growing season. Early in the day or late in the evening is the best time to sprinkle them.—J. L. E.

Woolly Aphis on Auriculas.—I do not think the woolly aphis, referred to on page 445, issue September 7, really does any harm to the plants, but at the same time it should be kept down, if only for the sake of appearance. I was particularly interested in reading Mr. Savory's remarks regarding the use of methylated spirit, and I can fully bear out Mr. T. Shepherd's statement. For the last three years I have employed it freely at the time of repotting, and later in the season used it around the collars of the plants whenever the woolly aphis appeared, and with good results. Tobacco powder is also effective, while if the frames are vaporised occasionally with N.L. All, those on the surface are destroyed. When repotting I always endeavour to use a fresh lot of pots, and quite clean crocks for drainage purposes. Auriculas

are growing exceptionally well this year, the cool, damp weather just suiting their requirements. This probably accounts for so many pushing up flower-spikes, particularly among the seedlings. Rose General Macarthur, referred to on page 446, issue September 7, has been covered with mildew for two months; but this is an exceptional season, and hitherto I have never discovered any of the disease on this really grand Rose.—S. T.

A Beautiful New Zealand Tree.—In THE GARDEN of June 8 there is, in an article entitled "Hardy Shrubs with Pea-shaped Flowers," mention made of *Edwardsia grandiflora* (*Sophora tetraptera*). This tree is a native of New Zealand, where it is very common even in the towns, while in country districts it is not an uncommon thing to see whole forests of it. With New Zealanders it heralds the coming of spring, as does the Daffodil in England. The Maori name for it is Kowhai, and the flower is singularly beautiful. It is of a deep gold colour, and the flowers hang down from the branches in great clusters. So popular has the flower become of late years that suggestions that it should be made the New Zealand national flower have been receiving a good deal of attention, and one or two towns now celebrate Kowhai Day as Wattle Day is celebrated in Australia. Kowhai comes into bloom here late in August or early in September. Its appearance is generally simultaneous with several days of wind and rain; hence the term "kowhai fresh" is often applied to bad weather in early spring. During these days the blossoms are considerably blown about, but they come out in full a few days afterwards and bloom for two or three weeks. It is a most beautiful sight to see a Kowhai forest in bloom in September.—MONA MACKAY, *Auckland, New Zealand*.

Good Trees for Autumn Tints.—The spell of dry, sunny weather experienced during September seems to have had the effect of developing the autumn tints to a much greater extent than at one time appeared probable. One of the outstanding features in the Botanic Gardens during the past two weeks has been a tree of the Sweet Buckeye (*Æsculus flava*). This tree changes to a most beautiful golden, almost orange, yellow, and never fails to give a delightful display every autumn. In no year do I remember the common Horse Chestnut giving a finer display. The leaves of this change in instalments, as it were, and patches of deep bronzy red have developed all over many of the trees. *Pyrus lobata*, or, as it is often called, *Mespilus Smithii*, changes in much the same way, the bright patches of red at intervals over the tree having a most pleasing effect. Every leaf of *Acer colchicum* is now changing to a delightful shade of yellow, and it continues to give its display over a fairly-long period. In no way behind it in point of beauty and effectiveness is *A. saccharinum*, the Sugar Maple. Other trees with yellow foliage, or changing to yellow, are *Populus nigra betulifolia*, more golden even than the Golden Poplar itself at this time. The Golden Catalpa must also be included, while the Elms, especially the common field Elm, will presently change their colour and don a garb of a most pleasing yellow. Among the trees with more brilliantly-tinted foliage, the Plum-leaved Thorn (*Cratægus prunifolia*) stands out conspicuously. The foliage of this is brilliant in the extreme, two finely-grown trees in the park here being the subject of much interest and admiration. When bearing a good crop of their large, deep red haws, the effect is greatly enhanced. *Parrotia persica* and *Rhus glabra*, with their glorious colouring, will presently

take up the story, while the many varieties of Japanese Maples are too well known to require mention.—J. D. HALLIBURTON, *Botanic Gardens, Bath*.

The Merodon Grub in Daffodil Bulbs.—I fear that many Daffodil-lovers may have an unpleasant surprise waiting for them next spring, as this pest seems to be very numerous this year. I have had consignments of bulbs procured from five different growers, and in each case have found one or more grubs in the stock. The chief points of interest appear to be these: First, that bulbs apparently quite sound in the middle of August were found "occupied" a month later. In one case I went over a stock of Citron on September 21, finding five grubs (two in one bulb). On the 27th, on a final overhauling before planting, three more were discovered, although the previous week's search had been very thorough. Secondly, bulbs which for any reason are damp seem to show signs of the grub more distinctly than when dry. Thirdly, that late planting, though in many ways undesirable, does give the grower more opportunity of making sure that his stock is sound. In this case it is not the "early bird that catches the worm." Lastly, I think that buyers should avoid blaming the growers if they find that any bulbs purchased include the grub, for it has been proved to me that the unfortunate grower, pinch he never so hard, cannot be certain of locating the enemy, who may reveal himself to the buyer a week or so later. I should like to add that in the case of twenty-eight bulbs infested, the grub apparently on each occasion entered by the base.—CAPTAIN.

An Experiment with Sweet Peas.—Being fond of experimenting in the growing of plants, and thinking I would try my hand at Sweet Peas, I did so in a small way this year for the first time. In February last I planted ten seeds each of eighteen varieties in boxes. Almost every seed came up and made a strong little plant (I got the finest seed procurable from an eminent firm, and they all came true). I planted them out in butter-tubs from the grocer in very rich, black soil, and stood them in a row on a sunny path in the kitchen garden. They had chemical and liquid manure, and their roots were always kept moist. At the beginning of July they were in full bloom, 8 feet high from the ground, and were in a thoroughly strong, healthy state. I cut off the blooms daily. The third week in July, when the weather turned very hot, the lowest leaves on the plants began to turn yellow, every day more of them, and then the stalk from the ground upwards. I watched them for about a week becoming a little more dried and yellow each day. When this state had reached about halfway up the plants, I took action. The tubs were carried into the deep shade of Cherry and Plum trees, and were stood, two or three together, where their tops just touched the lowest branches. All the buds were removed, fresh earth was put about the roots and the hose turned on to them. The hose was turned on three or four times a day. They were kept dripping wet, and often had a last hosing at nine o'clock at night. Some of the leaves were marked so that I could watch them. At the end of a week I began to notice a change in them, the yellowing ceased, the stalks began swelling and turning green again. They picked up rapidly, and I soon began feeding again. They have remained under the trees ever since, fine green plants. Some of them have run up into the branches, where I find it difficult to get the blooms. *Flora Norton*, *Royal Purple* and *Doris Usher* are still blooming well.—C. L. COX.

Calceolaria amplexicaulis.—On page 458, issue September 14, "F. G. P." has a note on the above-named plant. He is quite right in strongly recommending it as a good bedding-out plant. I wish to also draw readers' attention to the fact that this *Calceolaria* is excellent for flowering in a dwelling-room window and in a cold greenhouse. When so grown, the plants flower quite early in the season and make a fine display. Many years ago I first saw them growing in sunny windows, and they were certainly very striking. The rooted cuttings may be wintered in a cold greenhouse or in a frame facing the south.—G. G.

Rose Sunburst.—I note your correspondent's remarks *re* this variety on page 474, issue September 21, but I think after he has grown it for another year he will be pleasantly surprised. The peculiarity of Sunburst is that the centre bud for the first flower, or, as *Chrysanthemum*-growers call it, the "crown bud," comes paler than those for the second crop of flowers. It should be disbudded accordingly. Just as *Mme. A. Chateau* is the most ideal of the older Roses, comprising as it does all that is ideal in the great points of colour, habit of plant, perfume, form of flower and, not least, lasting qualities, so I believe Sunburst will prove the best in Roses of its colour, for, except in the above-mentioned one weak point, it appears to possess most of all those qualities that go to make a great Rose.—LAURENCE J. COOK, *Bush Hill Park, Enfield.*

Euphorbia palustris.—Though many *Euphorbias* are looked upon as dull plants, curious but not very beautiful, there are a few that stand out during their flowering season as some of the showiest of garden plants. Such is the large-growing species shown in the accompanying illustration. This season everyone who caught sight of the mass of brilliant yellow bracts asked, while still far from the plant, what that fine thing was. The tone of yellow is singularly vivid in sunlight, just the colour of a wash of pure gamboge while still wet, and the picture shows what a mass of flower-heads the plant bears. It is widely spread in Europe as a wild plant, but rarely seen in gardens. Mine was given me by that accomplished and generous gardener, the late Mrs. Robb, one of the many good things that she gave me, and now remind me of happy days in her wonderful garden at Liphook. Although the specific name suggests the bog garden for this plant, it thrives well in the ordinary border, and mine reaches some 4 feet in height when in flower, exceeding it considerably when the side growths spring up and reach above the seeding heads. That, perhaps, is its one fault—it takes up so much space after flowering by making so many and such long, barren side shoots. I cut away a great many of them, and the plant has never shown any resentment for such treatment as yet.—E. A. BOWLES, *Waltham Cross.*

FORTHCOMING EVENTS.

October 8.—Royal Horticultural Society's Meeting and Exhibition. Lecture at 3 p.m. by Dr. Charles Crowther on "The Influence of Atmospheric Impurities on Vegetation."

October 9.—East Anglian Horticultural Club's Meeting. Lecture by Mr. C. H. Fox on "Deciduous Flowering Trees and Shrubs."

October 10.—Royal Horticultural Society's Autumn Show of British-grown Fruits (two days).

October 11.—Annual Conference of Affiliated Mutual Improvement Societies at the Royal Horticultural Society's Hall, Westminster.

THE ROSE GARDEN.

NOTES ON NEWER ROSES.

IT is pleasant to be able to take up one's pen again and to jot down a few notes on such a topic, it was even pleasanter to be able, after nearly two years' existence without a garden, to start growing Roses again.

During the gardenless period one tried to realise that it was "better to have loved and lost than never to have loved at all," but it did little to compensate one for the wrench of parting with a garden that may have been a little one. Still, in my case it was particularly my own, having grown out of the side of a bare chalk hill. But that period is behind me. It had the advantage of compelling me to start afresh, and, with

ton in a garden that was formerly a gravel-pit, but with such soil as it possesses of the very best

All plants were pruned particularly hard, and with a few exceptions, where to do so would be contrary to experience and practice, I do not think 3 inches of growth was left above ground. With these preliminary remarks as to the general circumstances, I hope to be able to give readers my experience of all the newer Roses introduced during the last three years by the leading raisers in Great Britain and Ireland, as well as the best of the Continental raisers. I have also had the additional advantage of visiting this year the nurseries of many of the raisers and seeing the Roses and the new seedlings growing at their birthplace, an important factor when dealing with new varieties. I will first of all deal with the Roses capable of

EUPHORBIA PALUSTRIS, A RARE SPECIES, IN MR. E. A. BOWLES' GARDEN.

the help of some of my Rose-growing friends, to stock the new garden with only the choicest and best.

Planted in 1911, the Roses came through the winter without a single loss, and growing in maiden soil (the top spit of an adjoining meadow—that desideratum that is often asked for but so seldom obtained), they have done wonderfully well; and although the year has not altogether been ideal from the Rose-grower's point of view, yet we in Hampshire, with the exception of the extreme earliness of the season (I had Roses from April 19 onwards, *Rosa sinica Anemone* on a fence facing due east being in full flower on that date), have had little cause to grumble. The flowers, having been grown without a check, were of high quality and splendid colour.

The newer Roses, of which I had rather more than two hundred plants, did particularly well, and if these notes appear somewhat highly coloured, it will be due to that reason and that reason only. I shall endeavour, as far as I am able, to set down the behaviour of each plant as grown in Southamp-

ton producing exhibition flowers, and then the garden and decorative varieties, including climbers.

Southampton. HERBERT E. MOLYNEUX.

(To be continued.)

ROSE IRISH FLAME.

MESSRS. A. DICKSON AND SONS of Newtownards first gave us the wonderful Irish Elegance, which even now is one of the most popular of single Roses, and now they have produced this gem, which will be sought after for every garden. It is really remarkable that two gold medals should be awarded to two decorative Roses this year, and it speaks much for the popularity of this type of flower. As its name implies, Irish Flame is of that ruddy hue which among Roses, as indeed any flower, is ever welcome, and I can imagine that in the near future it will be used for table decoration, in conjunction with Old Gold and perhaps *Mme. Edouard Herriott*, something in the same way as *Lyon Rose* and *Irish Elegance* are used to-day.

DANECROFT.

MAKING A SMALL JAPANESE GARDEN.

[In Answer to a Correspondent.]

To make a small Japanese garden upon a plot of ground 24 feet by 20 feet is possible, but it will be extremely limited. If the ground is level, it will be well to throw up the soil after it has been thoroughly trenched, in order to secure more surface space in forming the design. We will assume that the centre, or thereabouts, is the present ground-level. If so, cast up the soil from one part to the other, so as to form a mound of earth of 2 feet or so in height. This will leave an excavation that can be arranged as a small pool. Do

AN INFORMAL GROUPING OF JAPANESE WINDFLOWERS FRINGED WITH HARDY CYCLAMEN. (See page 501.)

not attempt to make the design at all uniform or in any way balanced. The more informal it is, the better will be the effect when completed. It may be possible to fix a stone Japanese lantern to add to the effect. In the pool of water a small fountain-jet will add to the effect.

Upon such a limited space none but the smaller-growing and pigmy plants will be possible. For planting out, a few of the dwarf Abies or Pinus family might be used. One weeping tree, such as a standard of *Sophora japonica pendula*, would be effective. There might be room for a small plant of *Sciadopitys verticillata* (the Umbrella Pine of Japan); this requires moisture and a peaty soil. A few plants of *Iris Kämpferi* would be a distinct advantage. These should be near to, but just elevated above, the water. Upon such a space there would be no room whatever for any grass; in fact, a lawn does not enter into any but the largest arrangements. Some flat, informal stepping-stones for stepping upon, and nothing else, so provided, should be used. A few small plants in vases will, in such a limited space, be quite in keeping with the surroundings. Small Pomegranates and some tiny Acers in pots or vases will be suitable, so also, with care, will the *Retinosporas* and the Japanese Larch (*Larix leptolepis*). ANGLO-JAP.

THE FLOWER GARDEN.

SOME DAFFODIL CRITICISMS.

MAY I be allowed to make some comments on several matters contained in the interesting articles on Daffodils in your Special Bulb Number? First, I would like to endorse the commendation of Heroine by "Poeticus," as it seems to endorse my opinion, expressed last year, that "it is something better than an improved Albatross." Secondly, I challenge Mr. Shea's statement, "there exists now for the new-comer only the very barest and unlikely

if one of the most beautiful flowers (for I entirely agree with Mr. Jacob's commendation of Avalon) can come from flowers such as were its parents, why cannot the tyro hope still to score some similar success? This year I secured a wonderful blood red flat eye and a most up-to-date Poeticus from Mr. Engleheart, and I have some two hundred seeds from their pollen. Why may I not hope for something really good from such pollen used on thoroughly up-to-date flowers?

Again, there is always a possibility of getting a good thing from the crosses that might be thought to have been thoroughly worked out, as evidence my own third cross, producing King Cup from Golden Spur \times ornatus. No; the would-be hybridiser need not be put off from despair of producing something good, but let him start with good up-to-date flowers, not necessarily the very expensive ones, and work systematically, not being frightened by the work of "the men who had so very long a start," but let him take to heart the lesson taught by the play of "Milestones" and benefit by the past experience of others. By all means let him keep the most accurate statistics of his crosses and the results, as, if for nothing else, it lends interest to the hobby, and undoubtedly there is much in Mr. Shea's view that the compilation of statistics may be most valuable for determining points which are dealt with by himself and Mr. Jones.

I think Mr. Shea is nearer the mark than Mr. Jones as to the reason of the failure of so many crosses. I cannot quite follow Mr. Jones when he says "most of the pollen dried and dropped off before absorption." My idea has always been that if the stigma is in a receptive state, which means that it is sticky, when once the pollen has attached itself the impregnation has taken place, and no amount of wind will prevent the inoculation of the ova, and only a most abnormal amount of heat will prevent it; but if frost intervenes it is, to my mind, quite another matter, as in that case the whole fertilising powers are killed by the sun bursting the frosted anatomy of the style. This year I made some four hundred and fifty crosses, mostly on a small number of flowers in each case, and I obtained seed from about two hundred. Many of the crosses were on, and by pollen of, my own seedlings, many of the first year's flowering, and therefore entirely unknown quantities. I have analysed the results of the work on named flowers, but not my own seedlings, and the result is that out of one hundred and twenty-six trumpet crosses forty-seven were successful and seventy-nine failed, out of seventy-three Medio crosses four were successful and sixty-nine failed, and out of ninety-eight Parvi crosses ten were successful and eighty-eight failed. I have not taken my own seedlings, as without considerable labour of reference I cannot be sure of them being trumpets, Medio or Parvi. Roughly speaking, my results seem to support Mr. Shea's and Mr. Jones' suggestion that the trumpet flowers were more fertile this year, be the reason what it may.

One thing I noticed was the fecundity of maiden flowers. I hoped to restrict the number of seeds this year, as I find my stock of seedlings getting beyond my power to attend to; but owing to this fecundity I found a large number of my maiden seedlings that I had not worked on with pods full of seeds, and could not resist saving and sowing them, and thus adding largely to my stock of seed. A considerable number of them were late flowers.

I think the hope of the present-day hybridist, both among the veteran and the young recruits,

chance of producing new varieties at all comparable with those created by the men who had so long a start." With the concluding words of his paragraph, "they cannot now be overtaken," perhaps one must agree, as they have such an accumulation of good things that in a number of good things they must continue to lead, but I contend that there are plenty of chances of producing new varieties comparable with, and better than, those created "by the men who had so long a start." It must be remembered that, to begin with, the pioneers had to experiment with flowers of inferior size, substance and colour, and the present hybridiser has almost too many flowers that years ago would have been considered by the pioneers almost impossible of attainment. Mr. Shea's cry is the cry of despair, and is not calculated to encourage the would-be hybridiser, as the joys of a statistician are hardly those to attract the young hybridiser! I gladly welcome Mr. Shea's desire for statistics in our mutual hobby, but do not hold out that as the *only* inducement for continuing or becoming a Daffodil hybridist!

The article on Avalon seems to me to contain a most happy answer to Mr. Shea's pessimism. This beautiful flower is stated to be the result of crossing Beacon with a Poet. Now, surely

is the new seedling flowers. From quite an indifferent seedling from Almira with Thelena pollen I had a flower this year which I fondly hope may be considered to be "comparable" with some of the flowers in the present first flight. *Nil desperandum.*

Pendeford Hall, Wolverhampton.

SEASONABLE NOTES ON CARNATIONS.

Plants in Beds.—It is well within the bounds of possibility that all the Carnations rooted from layers put down in July and August have not yet reached their permanent positions, and, where this is the case, it is strongly urged that the work shall be accomplished immediately. In light, open soils which are pleasantly warm, the planting may be done later than on colder, close grounds; but in no case is it wise or desirable to defer the work any longer than is absolutely necessary, for the simple reason that the later it is finished, the less opportunity will the roots have to secure a satisfactory hold before the winter. Plants that were placed in their positions in the beds and borders a short time back will be established, and unless the conditions are peculiarly unfavourable, it is improbable that they will cause the grower the slightest anxiety or worry through the winter. It is, of course, more than probable that some of them will lift from the ground in severe frosts; but this is a contingency which the cultivator expects, and therefore he is ready to remedy it by replacing the plants as required.

Hoeing.—There are few, if any, details of cultivation in connection with these delightful flowers of more importance than hoeing, and, provided it is done carefully when the soil is in suitable condition, it is impossible to do it too frequently. In the first place, it opens up the surface of the soil, and thus facilitates the admission of rain, which is promptly followed by the invigorating and sweetening fresh air; and, in the second place, it positively prevents the establishment of weeds. It has been suggested that care shall be used in carrying out the work, and this fact must be impressed, since carelessness will certainly result in some of the plants being injured by the blade of the tool, and others will probably have their roots disturbed. Either condition of affairs is prejudicial to the continued satisfactory progress of the plants. It is essential, too, that no attempt shall be made to hoe when the ground is wet, but at any other time it may advantageously be done.

Surface Manuring or Mulching.—Where there is a plentiful supply of short, sweet manure, a surface dressing or mulching beneath the Carnations cannot prove otherwise than beneficial to the plants. The first thing is to loosen the surface with a hoe, fork, or even a bluntly-pointed stick, according to convenience, and then spread down the covering material. It is not wise to allow this to settle down into a close mass, as it is rather prone to do after heavy rains, as it then becomes impenetrable by water and air, thus creating a particularly undesirable condition of affairs; but this is easily obviated by occasional loosening with a small

fork or a pointed stick. In an open state it presents no obstacle whatever to the passage of rain-water, and if this can pass through, it is certain that fresh air will follow. There is, then, the additional advantage of the food virtues in the manure being carried down into the soil for appropriation by the roots of the plants when they are active.

Plants in Frames.—It has become the excellent practice to have a reserve stock of plants, especially of the choicest and yellow-ground varieties, in small pots in cold frames, because the losses in the winter may be rather serious, and are almost sure to be so with those of tender constitution in low-lying gardens where the soil is on the strong side. Among the plants thus treated, reasonable attention will ensure them passing the winter in perfect safety. The danger with amateurs lies in coddling. In no circumstances is this permissible. The more fresh air that can be admitted to the frames, the better the plants will thrive, and to this end the lights should be off whenever the weather will permit of it, and must never be quite closed, even though there be frosts or heavy rains. The latter do more harm than the former; hence the importance of some protection when they are falling. F. R.

BORDER FLOWERS IN EARLY AUTUMN.

The illustrations on this page and page 500 should prove of special interest to those who garden for

flowers, with sword-like foliage, are those of *Watsonia Ardernei alba*. These plants require much the same treatment as *Gladioli*, and succeed best when grown on a warm, sunny border. The flowers of both *Phloxes* and *Watsonias* are thrown out in bold relief against a dark background of hardy shrubs. *Gladioli* of the *branchleyensis* type might be used instead of *Watsonias*, as they flower about the same time. When planting the *Phloxes* in late autumn, room should be left for the *Gladioli* or *Watsonias*, which would be planted at the end of March or early in April. This is a simple effect that might well be carried out in many gardens where flowers at the fall of the year are appreciated.

EARTHENWARE RINGS FOR BULBS.

IN THE GARDEN of June 14, 1884, page 485, there is an article on earthenware rings for confining bulbs in borders. Can any of your readers tell me whether anything came of this suggestion? Were these rings ever manufactured and put on the market, and, if so, by whom? as it strikes me that many amateurs would, in the present day, be glad of such arrangements, if at all suitable, for the better regulating of their borders. J. P.

[As this is a subject that will be of general interest just now, we reprint below the article referred to by our correspondent.—Ed.]

EARTHENWARE RINGS FOR BULBS.

LIKE many other amateurs, I am fond of growing bulbous plants, but, owing to the fact that I have

A BORDER OF PHLOXES AND WATSONIAS FOR EARLY AUTUMN EFFECT.

September and October effect. The illustration on page 500 depicts an informal grouping of Japanese Windflowers (*Anemone japonica*) fringed with clusters of low-growing hardy *Cyclamen*. This happy effect is taken from Gunnersbury House Gardens, where Mr. Hudson, with his usual gardening skill, succeeds in obtaining beautiful colour blendings with autumn flowers and foliage. Japanese *Anemones* are particularly useful for growing under the shade of trees, while the autumn-flowered *Cyclamen*, *C. europæum* and *C. hederæfolium*, revel under such conditions.

The illustration on this page depicts a border of *Phloxes* and *Watsonias* at Kew. The *Phloxes* are mainly white varieties, but pale blues and pinks are also included. The tall spikes of white

limited space, and must needs grow them in mixed borders, and that when grown there their exact whereabouts often get forgotten, and in the moving of other plants and the necessary work of the border the clumps get "dug" in half and the bulbs scattered over the border, producing a most untidy effect, and that some bulbs like the *Tritonias* have a disposition to wander and come up in the heart of another plant, I gave up bulb-growing in despair till I thought if I got something that would be strong enough to resist the blow of a spade, and at the same time confine the bulbs to the space allotted to them, I might perhaps be able again to see my favourites in their old quarters. I went to our brickyard and asked the foreman when he was making 9-inch drain-tiles to cut me

off as the clay form issued from the machine 6-inch lengths of tile, and to burn them specially. On receiving them I at once planted my Tulips, Lilies, &c., in clumps in these rings; the result has been most satisfactory. The rings are plunged into the border 2 inches underground, and the bulbs planted in them and filled up, and they are safe. Their locality does not need marking, for when the spade is at work the ring proclaims its existence, and so is easily avoided. At the same time, being an inch thick, and supported on all sides by the soil, it cannot be broken easily. The advantages are that bulbs needing peat can be grown in a mixed border by merely filling up the ring with the necessary soil; the sides of the pot or ring prevent wandering roots from eating up the food intended for the bulbs.

Let us suppose that five Tulips are put in the first instance into a 9-inch ring; they can be left with advantage two years at least, by which time the size of the clump will proclaim, by the space it occupies, that the ring is pretty full of bulbs, and in the autumn, when the borders are gone over, the ring is just turned out with a clod of earth filling up its calibre with the bulbs which are shaken out, the largest returned, and the rest are stock in hand for the nursery or for giving away. As the rings are straight-sided and have no bottoms, the bulbs stand crowding well, as they can root downward without interruption into the border, and the usual autumn mulch feeds them as well, and the work of planting must not be done more than once in two or three years. I have now had others made of 6 inches and 4 inches in diameter for smaller clumps and smaller bulbs. The smallest size is used for edgings of small bulbs, such as Crocuses, Snowdrops, Squills, &c.; the larger ones do well for Lilies, Tulips, Hyacinths, Gladioli, &c. The 9-inch rings cost me 4d. each, and with ordinary care will last a lifetime; the 6-inch cost 13s. a hundred, and the 4-inch 6s. 6d. a hundred. They can be made at any brickyard, and if a greater demand was had for them, they might be made much cheaper, as they take up little room, and the three sizes can be nested together and take up only the room of the 9-inch ring, an advantage where they have to be sent a distance. They economise bulbs, as each little corm or bulb is easily found and preserved, and as the whole clump comes up with the ring, no stray bulbets get into the border to disfigure its neatness next season.

Nayland, Colchester.

H. D. PALMER.

ACHILLEA PTARMICA PERRY'S WHITE.

This is a new variety possessing many good qualities as a garden flower. It is a seedling of Achillea Ptarmica, with double snow white flowers about an inch across and produced in the wildest profusion. It is much larger-flowered than

either Bouquet or The Pearl, and its flowering season extends from June till late autumn. Growing over three feet in height, with stiff, rigid and much branching stems, it is without question a most useful subject for cutting or decorative purposes. This acquisition was raised at Mr. Amos Perry's Hardy Plant Farms, Enfield, Middlesex, and received an award of merit recently when shown before the Royal Horticultural Society.

A PAVED LAVENDER WALK.

In Old English gardens Lavender walks formed one of the most pleasing features, and those who are fond of old-world effects could not do better than introduce this feature in gardens of to-day.

ACHILLEA PTARMICA PERRY'S WHITE. A NEW DOUBLE-FLOWERED VARIETY INVALUABLE FOR CUTTING AND DECORATIVE PURPOSES.

Nothing could be more simple. Cuttings of Lavender root readily in the autumn if prepared from young wood and inserted in free, sandy soil under hand-lights, when they will be ready to plant out in the spring. Cuttings, when taken with a "heel," also root in the open in sandy soil, but the method of using a hand-light ensures success, and is generally preferred. The paved Lavender walk seen in the illustration on page 503 is a delightful feature of the gardens at Regal Lodge, Kentford. The bold lines of Lavender are edged with Thyme, while between the paving-stones are many little tufts of dwarf Campanulas, chiefly C. pulla and the variety Miss Willmott,

THE ROCK AND WATER GARDEN.

ROCK GARDEN PLANTS THAT FLOWER IN EARLY AUTUMN.

EVERYTHING—be it Rose, or alpine plant, or what you will—has its season, and when that is past, when the fulness of the beauty is gone, what remains, welcome though it be, constitutes but fractional parts of the greater whole we remember so well. Of no section of plants is this more true than that we know as alpine, and which inclines to yield of its fuller wealth of beauty and variety before the year has more than half run its course. Those that come to us after that time, despite their individual charms, are but few and far between, disjointed members, as it were, of a great flowering chain that had remained unbroken for months.

The passing of June, however, is usually the signal for the snapping of the last link in the chain, and though by that time alpinists should have had a good innings, yet they appear never to be quite satisfied—to be wishful for more of the wealth of spring, even amid the breath of parched July or even later. That this is the condition of things existing in most rock gardens at the time indicated few will attempt to gainsay, though it is a moot question, I think, whether the fault is not a little on the side of the planter, who, encouraging the greater flower wealth of spring and early summer, discourages—if all unwittingly—the lesser wealth that follows by and by.

In the earlier months of the year we see the incomparable flower pictures of alpine Phlox, Aubrietia, Dianthus, Candytuft and so on; but is there one among the number to surpass a spreading, well-flowered mass of the rosy pink *Convolvulus althæoides* of July? But we do not see it, or certainly only rarely, and then not always in good condition. It may be—indeed is, probably, that our rock gardens are not big enough for all—not big enough to provide representative pictures of all that is good; hence the comparative rarity of some. At Friar Park I have seen this unique subject in its fullest glory; but there is elbow-room there and the owner knows what is good. There is room, too, at Wisley, and plenty of it just now, and a few yards square of the plant well in flower would be worth a day's journey to see. Moreover, it would give fresh impetus to the cultivation of a too-little-known plant. And there are Campanulas, too—one might almost enumerate a dozen such—*Zoyssi*, *Tymonsii*, *garganica* and its forms, *fragilis*, *isophylla* and its varieties (hardy enough and perennial enough if planted in chinks of rock instead of the richer soil in the pockets), *Stansfieldii*, *White Star*, *Profusion*, to say nothing of the later-flowering varieties of the turbinate

group—which are worthy of a little more thought from those who would embrace the longest possible season of flowering. Then there is the wild *C. rotundifolia*, or Harebell, a charming plant that is worthy of inclusion in the best rock gardens where flowers are required during July and August.

In not a few instances the owners of large gardens are absent from home for weeks after midsummer, when but little encouragement is given to subjects flowering after that time. These and other things might readily constitute contributory causes for the absence of some plants and the unrepresentative display of others during some weeks of the latter part of summer. What is needed most of all, perhaps, is a rock garden on a more representative plan planted with a view to do justice to all, rather

Lysimachia Henryii and *Wahlenbergia vincaeflora*—plants of undoubted merit and utility—may all be added to the lists of late summer alpine flowers, growers of such things have no cause for repining, and much less for despair. At the same time, there are good plants other than novelties or reintroductions meriting all consideration, and one recalls *Zauschneria*, *Polygonum vacciniifolium* (a rock-draping mass of this almost challenges description), *Gentiana septemfida*, *G. Andrewsii* (good in its unopened bud colour), *Sternbergia*, *Crocus*, *Cyclamen* and others which might profitably be used to prolong the season of flowering in this department. Just what is available and what most useful are questions worth pursuing, while of even greater moment is the increase of some.

THE GREENHOUSE.

MINIATURE HYACINTHS.

THERE is no doubt the trade in Hyacinths in Holland is nothing like what it was twenty-five or thirty years ago. Daffodils and "taste" account for the decline. Ask any old firm round about Haarlem or Hillegom how many Daffodils they grew then and how many now? The flower-lover of the twentieth century must have Daffodils in his garden and in his greenhouse, and someone has to supply him with bulbs. Again, the tide of taste has changed. The formal has given place to the informal, and heaviness to

A PAVED LAVENDER WALK WITH TUFTS OF CAMPANULAS GROWING BETWEEN THE STONES.

than, as is often the case, to permit the free-flowering and showy to predominate, to the exclusion of much else that is good or even more worthy. In private gardens, naturally, the season of greater gaiety is at the direction or wish of the owner, while at Kew or at Wisley, whither gardeners and others go for inspiration and education, the idea of more representative planting, as opposed to display work covering shorter periods of time, might reasonably receive studious thought.

In certain directions late-flowering alpine plants are asked for—almost clamoured for—hence there is need to look around to see what is to be had. Each year, too, is giving evidences anew that the supplies are not exhausted; and when in a single season such good things as *Astilbe simplicifolia*,

The following are among good things worthy of consideration, though the list makes no pretence at completeness: *Campanulas waldsteiniana*, *Zoysii*, *Profusion*, *Stansfieldii*, *fragilis*, *isophylla*, *garganica*, *Tymonsii*, *White Star* and *rotundifolia* (Harebell), *Cyananthus lobatus*, *Erigeron mucronatus*, *Polygonum vacciniifolium*, *empetrifolium* and affine (*Brunonis*), *Lysimachia Henryii*, *Saxifraga Fortunei*, *Zauschneria californica*, *Gentianas Andrewsii* and *septemfida*, *Sternbergias*, *Crocus* species in variety, *Sedum spurium* in variety, *Ceratostigma plumbaginoides*, *Silene alpestris*, *Mesembryanthemum uncinatum*, *Androsace lanuginosa*, *Wahlenbergia vincaeflora*, *Achilleas* in variety, *Acanas* and *Eriogonum umbellatum*.

Hampton Hill.

E. H. JENKINS.

lightness. The stiff spike of the Hyacinth has been steadily declining in popular favour.

For some time now I have been preaching to the bulb-dealers of Holland as their means of salvation miniature Hyacinths. The invariable answer was, "They won't pay to grow." I think they must have found out they were mistaken. Every 1912 list that I have taken up has them in, and I am told by the wholesale growers that the sales of these small bulbs have increased enormously during the last two or three years. Except for showing in competition they are suitable for every purpose for which the large ones were formerly used. Out of doors they are not so top-heavy, and do not need quite the same care in staking. In pots they are lighter-looking, and three miniatures

in a 5-inch pot are less stiff and formal than one large fat spike. Their culture is precisely the same.

A point of interest is the *depth* of the pot or pan. I have long come to the conclusion that the ordinary ones are too deep, especially in the larger sizes, and that all Tulips, Hyacinths and Daffodils look far better in shallower ones. I think readers will agree that there is not much wrong with the miniature Hyacinths illustrated on this page. It will be noted that the pot used is one of those which I am advocating, and that its diminished depth has been no detriment to their growth. It may also be seen that it has a glazed surface, and that it rests on a special shaped stand. This latter I invented to take the place of the usual saucer or plate. It is much neater and is just as effective. The glazed pot is provided with ordinary drainage like any other. It is brown in colour.

As the culture of the miniature Hyacinths is the same as that of the larger and older bulbs, so there is no difference in the varieties. A miniature L'Innocence is really a two or three year old bulb, when second size and top size are two or three years older still. The following is a good selection: White—Albertine (early), L'Innocence, and Mr. Plimsoll (palest blush); pink—General de Wet, Charles Dickens, Lady Derby and L'Ornement Rose; red—General Pelissier (early), Roi des Belges, Homerus (rose, very early), Gertrude and La Victoire (early, new and very fine); dark blue—King of the Blues, Marie and Baron van Tuyll; pale blue—La Peyrouse, Johan, Lord Derby and Schotel; mauve and violet—Lord Balfour and Sir William Mansfield; yellow—Fleur d'Or and Yellow Hammer. JOSEPH JACOB.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Woodroffeæ (O. Rossii rubescens × O. Queen Alexandra).—The sepals and petals of this handsome form are of brownish crimson irregularly barred yellow and cream. The purplish lip is emphasised by a white disc. It is a most distinct hybrid. From Mr. E. H. Davidson, Twyford.

AWARDS OF MERIT.

Odontoglossum Neptune (O. crispum × O. nebulosum).—The sepals and petals are white, with crimson blotches. The lip is also white and irregularly marked crimson.

Odontioda Margarita (O. madrense × C. noetzhiana).—This is one of the most distinct hybrid Odontiodas we have seen, the flowers having the unmistakable colour combination of some so-called pink-flowered Snapdragons, and in which pink and brown and yellow combine. These two fine novelties came from M. H. Graire, St. Fuscien, France.

Cattleya Lord Rothschild albescens.—A very handsome variety of large size. The wide, winged

sepals and petals are white, the bold, fringed lip of golden hue, heavily veined purple and tipped with pink. A very striking and beautiful novelty. From Messrs. J. and A. McBean, Hayward's Heath, Sussex.

Lælio-Cattleya hastediana (L. Henry Greenwood × C. aurea).—The sepals and petals are of a lustrous rose colour, the crimson lip being heavily fringed and freely reticulated with gold at the base. Exhibited by Mr. C. J. Phillips, The Glebe, Sevenoaks.

Zygopetalum maxillaria sanderiana.—In this distinct variety the sepals are of an intense

pink, and should be effective under artificial light. From Mr. J. T. West, Brentwood, Essex.

Dahlia Johnny (Pompon).—A model-formed flower of maroon crimson shade. From Mr. J. T. West, Brentwood.

Dahlia Mrs. Randall (Cactus).—The predominant colour is rosy cerise, the tips of the florets creamy white, the bases of buff yellow tone. From Messrs. James Stredwick and Son, St. Leonards.

Dahlia Jenny Wrenn (Garden Cactus).—The flowers are moderately large, the florets pink-coloured, with yellow bases. Exhibited by Messrs. James Stredwick and Sons, St. Leonards.

The foregoing Dahlias, having been adjudicated upon by a joint committee of the Royal Horticultural Society and the National Dahlia Society, carry the award of merit of the former and the first-class certificate of the latter.

Chrysanthemum Mrs. Joan Carter (Single).—The colour is a rich butter yellow, the flowers of medium size. In spray form it was most attractive. From Messrs. William Wells, Limited, Merstham.

Chrysanthemum Framfield Early White.—A pure white of much merit, the crisp, paper-like rustle of the petals denoting long-keeping qualities. From Mr. Norman Davis, Framfield, Sussex.

Pentstemon Mrs. F. Fulford.—Almost a self crimson throughout, a variety of large size and high decorative excellence. From Mr. Fulton, Tarnbolton.

Rose Little Dorrit (Tea).—Quite a charming variety of a rosy peach shade, with salmony and buff suffusions. It is delightful in the bud or expanded flower, presenting quite a variety of shades in these from day to day. Exhibited by Messrs. G. Paul and Sons, The Old Nurseries, Cheshunt.

Rose George Dickson (Hybrid Tea).—A giant among Roses of all sections, a veritable peer among its fellows, and one obviously of an epoch-making character. Already a gold medallist of the National Rose Society and the recipient of honours wherever shown, this magnificent variety is destined for great popularity. It is, as it were, the very embodiment of all that is good in such as Horace Vernet, Charles Lefebvre and others not far removed

which combine the most intense of crimson-scarlet shades.

Rose Mrs. Mackellar (Hybrid Tea).—Another superb variety of creamy yellow tone and pleasing fragrance.

Rose Edward Bohane (Hybrid Tea).—This is of giant proportions and of cherry red colouring. As a bedder it should prove a most attractive sort. These three novelties were exhibited by Messrs. Alex. Dickson and Sons, Limited, Newtownards, County Down.

The foregoing plants were shown before the Royal Horticultural Society on September 24, when the awards were made.

MINIATURE HYACINTHS IN A GLAZED POT WITH STAND TO MATCH.

olive green shade and irregularly blotched dull purple. The frontal lobe is of large size and of the purest white, with violet-coloured base. Exhibited by Sir Trevor Lawrence, Bart., Dorking.

Kniphofia John Benary.—This is one of the most brilliant and attractive of the late-flowering Torch Lilies, the colour being a brilliant orange scarlet. The plant is between 5 feet and 6 feet in height. From Messrs. James Veitch and Sons, Limited, Chelsea.

Dahlia Useful.—The name is somewhat suggestive of the variety, which is of the garden decorative type and of medium size. The colour is rosy

GARDENING FOR BEGINNERS.

GREASE-BANDING FRUIT TREES.

AMONG the numerous pests which attack fruit trees, few are more annoying than the spring caterpillars. After a fine show of blossom and a good set of young fruit, a bad attack of this troublesome pest may cause nearly all of it to be shed on account of the leaves failing to supply the necessary food at a critical time.

1.—HOW TO FIX THE "MULTI- PLEX" BAND TO THE TREE STEM. SEE THAT ONE EDGE LAPS WELL OVER THE OTHER.

It is, of course, possible to spray at this juncture, but the material required is a deadly poison—arsenic—and it will, therefore, in most cases be advisable to take measures to check the pest at another season and in another manner where possible.

The alternative method is that of grease-banding. The larvæ which do most damage are those of certain winter-flying moths, which pair and lay eggs during the early autumn and winter; and from the fact that the female is wingless comes the success of this method of grease-trapping. The chrysalis, having spent the summer in the soil, hatches out from October onwards, and the female climbs the tree and lays her eggs on the younger branches, and these eggs, at the approach of spring, hatch into the destructive caterpillars which are only too well known to gardeners. The essential point of the system is to have a grease which keeps sticky during the longest possible period. The greases generally sold do not, unfortunately, last longer than about two months, and it is therefore necessary to renew them from time to time. A preparation called "Tanglefoot" is now, however, on the market, which will keep in a sticky condition for nearly a year—certainly long enough to catch all the winter moths. The only objection to it is that of cost, it being many times more expensive than the ordinary greases. When, however, efficiency is considered, it is well worth the extra price.

The second important point is that of the paper. Any soft paper will, with the winter rains and winds, soon be torn and useless, and a tough waterproof paper is therefore necessary. This is cut into suitable sizes to encircle the trunk of the tree about four feet from the ground if standard trees are to be treated, or lower if with shorter stems. Allow enough paper to fold it over double at the joint, or it may blow apart in strong winds. Also for the same reason the joint should

be on the side away from prevalent winds. The paper is then tightly tied about one inch from both top and bottom, choosing a position where the bark is smooth to prevent the insects from walking up between the band and the tree.

The grease is then applied with a flat piece of wood about an inch wide. A mistake is often made in getting too thin and wide a layer. A small, thick layer resists evaporation much better and is just as effective, one 2 inches wide being excellent. Slight difficulty has been experienced in some cases in applying "Tanglefoot," as it is rather more viscid and less mealy than the grease. If care is taken not to put too much on at a time, it will be found to spread fairly easily. The band is now ready and requires no further attention except, in the case of the grease, a monthly visit to see if it is still sticky. If good material is used and thickly spread, it can be stirred up with a stick and a fresh surface exposed. A convenient band has been devised in Germany and sold in this country under the name of "Multiplex"; this not only serves the above purpose, but also acts as a trap for the larvæ of the Codlin moth and the Apple blossom weevil. The maggot of the Codlin moth, which is found in Apples, passes the winter in crevices of the bark in the chrysalis state, and the band, having an inner surface of corrugated paper, provides a suitable resting-place for it and the weevils when they ascend the tree in search of shelter. The band is then taken off and burned to destroy them in the spring, before they hatch out to lay their eggs on the young fruits. The outer layer of waterproof paper is specially made to take grease, the band thus serving the two purposes. The method of fixing the band is shown in the first illustration. This band ought to be put on in June for the Codlin moth, and it can then be greased in October and burned in the spring. If the Apple blossom weevils are troublesome, the band will trap these as they ascend the tree. Thus with this new band we have it on the tree nearly all the year. Early in October it is advisable to put on the bands and to have them greased as a trap for the

2.—APPLE BLOSSOM WEEVIL. THE LARVA OF THIS IS TRAPPED BY GETTING BETWEEN THE INNER AND OUTER PAPERS.

winter moth. The same bands may, if necessary, be left on to catch the weevil and Codlin moth larvæ. In the March following the bands should be burnt, and new ones put on the following June to take their places.

PROPAGATING BEDDING CALCEOLARIAS.

THE cuttings may be inserted any time from the middle of September to the middle of October. Although many thousands of cuttings are taken quite a month earlier, the resultant plants are not often as good as those raised from cuttings put in later. The wood of the Calceolaria is somewhat hard during the summer and the very early part of autumn, and when such wood is inserted it does not callus and form roots as soon as the cuttings made of softer wood. The best shoots for cuttings are those found near the base of the old plants, and it suffices if these are merely slipped off by gentle pressure with the fingers and thumb of one hand. The end of the stem should then be made smooth by paring it off with a very sharp knife. Usually these cuttings are inserted in frames facing the north, and, although they do fairly well in them, I believe in putting them in a frame facing the south. There is no strong sunshine from the date of insertion until the following spring, and only a light shading is needed. The cuttings root readily enough, and in the warm weather of springtime they grow very sturdily and are not drawn up as weakly as those grown for so many weeks in a north aspect. The bed should be composed of loam, leaf-soil and sand, with sand on the surface half an inch deep. Make all firm, insert the cuttings 3 inches apart each way, water, close the lights, and shade from any bright sunshine for a few weeks. When roots form, ventilate freely. A cold frame has many uses in the winter months. No amateur should be without one, and for striking Calceolaria cuttings it is all that can be desired. It is important that sturdy cuttings should be selected; then, with a reasonable amount of care, success will be ensured. **B.**

3.—THE CODLIN MOTH. THE LARVÆ WILL SPEND THE WINTER BETWEEN THE TWO LAYERS OF PAPER AND CAN BE BURNED IN SPRING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Lobelia cardinalis.—To preserve this plant through the winter months the roots should, when the plants have had their foliage spoiled by frost, be lifted, the stems cut off and stored in a box in leaf-soil or old potting material, and placed in a cool house and watered in. Afterwards little water will be needed, and, whenever possible, a free circulation of air should be given to prevent damping off.

Autumn-flowering Chrysanthemums.—Late-blooming varieties should, if possible, be protected at night from frosts, and the covering removed by day. Cut off any faded blooms, see that the plants do not lack support, and generally keep as tidy as possible. The Pompon varieties are not nearly so fashionable or frequently met with, but are attractive when planted at the foot of a wall, where, except for an occasional division and looping up of the growths, they are very little trouble.

Tuberous-rooted Begonias.—When the growths are cut down by frosts, the tubers, if required for another season, or perhaps the best of them that have previously been marked, may be lifted and placed for a few days or so in a light position under cover, so that the tubers may become thoroughly ripened before storing away for the winter and the foliage more or less naturally parted.

East Lothian Stocks.—I fully intended to mention a week or two earlier the autumn sowing of these. If not already done, sow seed at once in a box or pan of fine soil and place in a cold frame. Then, as soon as the seedlings are large enough, transplant into a frame or boxes and winter until the opportunity arrives for planting in the spring. For continuance of blooming these are indispensable, and their good growth admits of the greater number of the singles being removed as soon as visible, thus allowing the doubles a greater amount of space to develop.

Plants Under Glass.

Zonal Pelargoniums.—When housing these plants they should be placed as near to the glass as possible and not be overcrowded, otherwise the growth made will be weak and the resulting flowers poor. Avoid overwatering, but occasionally assist the plants with stimulants, and for a time avoid too dry an atmosphere. Look out for the small green caterpillars, which soon play havoc with the foliage. If they cannot be seen, they may often-times be dislodged by holding the pot firmly, the foliage downwards, and giving a sharp tap to the pot with the other hand.

Liliums.—Pot up the bulbs as soon as they arrive and stand closely together in a cold frame. They like a compost of good fibrous loam enriched with some powdered cow or sheep manure, with the addition of a little leaf-mould, finely-crushed charcoal and sand. Avoid overwatering until growth is fairly active. When potting, keep the bulb towards the bottom of the pot, so that there is room afterwards for top-dressing.

The Hardy Fruit Garden.

Picking and Storing Fruit.—Though I have once before made reference to this, I would like to add a few remarks concerning this important work. Picking should be proceeded with as the fruits become ready, choosing dry weather, and when the fruits are dry also. Handle as carefully as possible, and where space permits lay them out in a single layer. The patent trays that fit one upon the other are, I consider, ideal, especially for those who have limited room, as they are very compact and admit of a free circulation of air between the fruits.

Strawberries.—If the land has only just become vacant, planting of late runners rooted in 3-inch pots may still be carried out. A small plantation may be made to follow flowering subjects, such as Sweet Peas and Pentstemons. A complete change in this manner often results in a good growth after first breaking up the ground and giving a dressing of manure.

Fruits Under Glass.

Peaches and Nectarines.—Trees that are growing in unheated cases should, as soon as the fruits have been removed, be thoroughly well syringed,

and also watered if it is thought at all necessary. Abundance of air by day and night will help to thoroughly ripen the foliage and harden the growth, and where the lights are portable, by all means remove them entirely, unless they have to shelter plants.

Late Grapes.—Just a little fire-heat, and especially during damp weather, will help to keep the bunches in good condition. Any extra shading that was used above the foliage for helping to colour black Grapes may now be removed. A covering of straw over the borders will greatly assist in the prevention of evaporation, as well as giving the house an attractive appearance.

Preserving Grapes.—Where it is not convenient to allow the bunches to hang on the Vines, they may be well preserved by the use of bottles of water. There are one or two inventions on the market for this purpose; but, failing these, the ordinary pint and a-half wine-bottles will be found to answer the purpose admirably. They should be filled with pure water, and a pellet or two of charcoal will help to keep the water pure. Cut off the bunch with a portion of the old wood attached, and see that the stem touches the water.

The Kitchen Garden.

Spring Cabbage.—Continue to plant out the later seedlings on vacant ground, and as the work proceeds give a dusting of soot. Those that were put out last month should be assisted by frequent hoeings to ensure good plants before winter sets in.

Celery.—The work of blanching will now be in progress for the later supplies. This work entails a good amount of labour, but to ensure its good quality it must not be done slipshod. Choose fine weather and when the plant is dry, and stretch a line on either side of the row. Before commencing to earth-up see that the sticks are freed from any defective leaves and side growths. Break up the soil finely and well work in among the plants, holding the stalks together firmly so that no soil finds its way among them. For this reason, where it can be done, three men should be employed, one to walk backwards and attend to the plants, and one on either side of the row to break up the soil. This, of course, greatly expedites the work, and is really economy in working. Do not hurry to blanch the latest supplies, as the later this can be done the better the keeping properties.

Parsnips.—These need not be lifted entirely like many of the other root crops, and, being perfectly hardy, the bulk may be left in the ground, as then they are considered sweeter and better flavoured.

E. BECKETT, V.M.H.
Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Rose Cuttings.—These may be taken at any time now, choosing shoots about a foot long and inserting them 9 inches into the ground. They must be made quite firm, when frost will have no effect on them, and dry weather very little in late spring. The hybrid wichuraianas in particular strike root very freely, and they even flower the first summer; but many other Roses may be propagated in the same way. Well-matured young wood is essential.

Lifting Plants.—A watchful eye must be kept on the weather, and if plants are not protected on nights when frost is imminent, those that are wanted for another year should be lifted before being frost-bitten ever so slightly. In all cases employ pots small for the size of the plants, and as a rule it is better to stand them in a protected position out of doors for a few weeks rather than house them immediately. Some plants can be grown into quite large specimens from young material; *Calceolarias*, for instance, and these need not be preserved.

Agapanthus.—These winter well in a frost-proof structure with plenty of soil packed round and between the balls of roots. They ask for no water for months. If stock is wanted, one or two flower-heads may be left to mature seeds, seedlings growing very rapidly and producing stronger flowering plants than can be secured by divided old ones.

Sweet Peas.—Failure to bloom has been the general complaint this year, and it may be worth

while to consider the advisability of depending for effect on the grandiflora section, which has been fairly floriferous, notwithstanding the unsuitable weather. Seeds for strong flowering plants may be sown at once, care being taken to cover the pots with something that will prevent mice reaching the seeds.

The Plant-Houses.

Chrysanthemums.—The whole of those yet out should be transferred to empty structures during the incoming week. They may be effectively grouped in colours, but must not be stood too closely together, otherwise mildew will cause the leaves to drop. Give abundance of air in the meantime, closing only in the case of frost. The amount of water must be apportioned to their changed conditions; but overwatering, it should be remembered, though apparently innocuous, has an evil effect on the keeping of the blooms when cut. Clear manure-water and very slight applications of sulphate of ammonia are valuable colouring agents.

Bulbs for Pots.—The remainder may now be placed in pots. Usually they comprise only early Tulips and Hyacinths, but Darwin Tulips and Parrot Tulips and a selection of early Gladioli, e.g., The Bride and Ackermannii for cutting, and early Spanish Iris, such as Belle Chinoise, are also well worth growing. Store the filled pots in a protected position out of doors and cover with cinders or Cocoa-nut refuse. As a rule they will be ready for removal about the New Year.

Late Asters.—In the majority of gardens late Asters will not bloom if left out. The flowers are so valuable that at least a selection should be lifted and placed in pots or boxes, to be stood in any cool structure till the flowers are over. Once fresh roots push, they do not resent being in a warm greenhouse, but the colours are not so fresh as when expansion takes place in a perfectly cool place.

The Vegetable Garden.

Onions.—These will now be well enough ripened to store for the winter. Frost does not seem to harm the bulbs; but dryness, with fresh air, is essential to hinder them from pushing shoots and roots. I grow the largest proportion of James' Keeping, which is easier to ripen than very large sorts, and therefore keeps better.

Beet.—The crop may now be carefully lifted, the leaves twisted off and the roots stored away in sand in a frost-proof outhouse, or else clamped like Potatoes, with plenty of dry straw between the roots and the upper layer of soil. Dig or trench the ground after it is cleared, burying the leaves in the process.

Lettuces.—It is time to transfer plants not too forward from the open to frames for winter use. Sowing after sowing failed in August, and unless some were sown in frames or boxes, there will be a scarcity. Much may be effected by sowing in cutting-boxes at intervals and using the tender leaves when large enough. All the Year Round is one of the best for this purpose.

Cauliflowers.—There is often a glut at this time of the year, but the heads can be kept for some time if the plants are drawn and hung up in a very cool place. It is important, too, to protect those not lifted with a large leaf, which keeps them from losing colour and being damaged by bad weather.

The Hardy Fruit Garden.

Fruit-gathering.—All except the very latest Apples and Pears may be picked within the next ten days. King of the Pippins, Ribston Pippin and others that come on by degrees should be looked over twice or thrice weekly, and such Pears as Marie Louise, Emile d'Heyst and others that mature in the same way should be similarly managed. The fruit is not only finer flavoured, but the season of each is considerably extended when the gatherings are many.

Trees on Grass.—Grass has been so luxuriant that some of it has been mown two and three times. It should now be mown for the last time, when the orchard will be tidy for some months on end, except when the falling leaves make a litter. The finest fruit and the healthiest trees generally grow here on ground sown down with grass. It has the advantage of producing two crops, one of bulbous flowers and the other of fruit, and is easier to keep even in such an exceptional year as the present than bare soil.

R. P. BROTHERSTON,
Tynningham, Prestonkirk, N.B.

NURSERY NOTES.

THE WARGRAVE PLANT FARM.

SUCH is the style and title of an entirely new plant nursery which, during the past year, has sprung into being in the clear, open and pure country atmosphere between Twyford and Henley. Its immediate position is on the main Bath Road, a mile or so from the Twyford and Wargrave Stations (Great Western Railway); while to the pedestrian or motorist from the Reading side it is presented to view on slightly-elevated ground at a right-angled turn half a mile or more ahead, about midway between the places named. Hence, at the outset, there has been no idea of "hiding the light under a bushel"; rather has there been a studied and businesslike attempt to reveal its whereabouts to all whom it may concern.

This, then, is the brief introduction we present to our readers of the new-comer, though an equally important obligation remains, viz., to introduce its promoter and proprietor, who is Mr. Bernard Crisp, a son of Sir Frank Crisp of Friar Park, Henley-on-Thames. In this solitary fact prestige and importance participate, the former of a purely personal nature, the latter because this particular beginner's experiences have been founded upon a rock—that at Friar Park to wit—and not been built upon the sand. Schooled in such a university, it is little wonder that Mr. Bernard Crisp has invested this new venture of his—a realisation of the dream of years—with a knowledge and enthusiasm which are of considerable rarity, and which will doubtless stand him in good stead as the years go by. Already there are some six acres of recent pasture-land within the enclosure, with opportunities for liberal extension. The plants already installed in the nursery beds—and they exist in their thousands—evidence unusual vigour and freedom, and there appears little room for doubt that the vast majority of plants such a nursery should contain will presently find here a highly-congenial home.

Flanking right and left within the crescent-formed entrance are broad stretches of *Nepeta Mussini*, a highly-attractive plant with bluish violet flowers. From this point spacious herbaceous borders prevail, acting as conductors to what is beyond. In these, for the most part, many goodly examples are to be seen, *Heleniums*, *Polygonums*, *Kniphofias*, *Sunflowers*, *Michaelmas Daisies* and similar kinds, and adjacent thereto collections or selections of these and other plants galore, the aim of the moment being to get together, test, and presently retain the fittest of each. In order to carry this into effect, much space is devoted to *Flag* and other *Irises*, to *Phloxes* of the *decussata* or herbaceous set, to *Michaelmas Daisies*, and, in turn, to all other large classes of plants. What appealed to us most strongly, however, was the great range and variety of alpiners in plunging-bed or frame—they were present in their battalions, and the nursery is obviously destined to be a veritable emporium for such things. Nor were the plants mere fragments of their kind; on the contrary, they surprised us by their representative character and good and sensible size, such, indeed, as are calculated to endure and to conform to the guarantee which the published catalogue gives concerning them. Obviously such a collection and such plants are not the work of a day, and obviously, too, Mr. Crisp gardened with these things in days before the nursery began.

Amid thin, sheltering hedges of Beech and in prepared soil we got quickly into touch with the choicer subjects, and here in their hundreds were many plants being raised from seeds. Of these, quite a revelation was a batch of *Primula capitata* in full flower within ten months of the sowing. The variety, too, was a particularly good and rich-coloured one, taller—12 inches to 15 inches for the most part—and perhaps a trifle more frail of stem than is the typical kind usually. The fine, free mass of it in early September days was most welcome, and rock gardeners and others who require this good plant at that time should make a note of it straight away. *P. bulleyana*, *P. littoniana*, *P. frondosa*, *P. Forrestii*, *P. denticulata* and its varieties *cashmeriana*, with *P. rosea* and many more, were all here upon the same plan, though not affording the conspicuous flowering of that first named. *Gentians*, too, are being raised from seeds, with more or less success, also the best of the alpine *Anemones*, such as *A. alpina*, *A. sulphurea*, *A. Pulsatilla*, *A. P. alba* and others. These latter are here in endless numbers, the seedlings constituting a veritable sward upon the ground. They are destined for further trial, however, the white form more particularly to ensure nothing but the best stock being distributed, a principle to which considerable importance is attached.

In these same shelters—veritable nurseries for the choicest children of garden and mountain—we came upon a capital grouping of *White Star Campanula*, whose white, salver-shaped flowers are 2 inches across on plants not more than eight inches high. It is a great beauty, and full of flower. The *Worm Grass (Spigelia marilandica)*, in crimson and gold; *Anemone sylvestris grandiflora flore pleno*, that inimitable carpeting alpine; *Linnaea borealis canadense*, whose exquisite drooping flowers of rose pink and white dangling as tiny bells from frail 3-inch-high stems beckon by their perfume alone; with *Soldanellas*, *Pratias*, *Spiraea digitata nana*, pink-flowered; *Lobelia radicans*, whose violet flowers have yellow spots and a white throat; *Wahlenbergia serpyllifolia major*, *Myosotis rupicola*, the true alpine *Forget-me-not*; and the rarely-seen *New Holland Violet (Erpetion reniforme)* were all here worthy representatives of their kind. Quite interesting and beautiful and new to us, as we believe it is to commerce, was the grey-leaved, yellow-flowered *Alyssum moellendorffianum*. It is of prostrate habit, late-flowering, and therefore valuable.

Quite naturally, in its more popular sections the genus *Saxifraga* predominates, and scores of the best, with choicer kinds in the hands of the propagator elsewhere, are sufficient for all purposes, sufficient to enthuse the visitor of their worth, their endless variety and their charm, and all-sufficient for those who garden with the best of them in alpine house or rock garden. Quite one of the more notable features of the nursery, however, are the rich collections of grey or silver leaved plants that crop up in all directions, whole groups of silvery *Artemisias*, *Achilleas*, and, in lesser degree, *Teucrium*, *Veronica*, *Pyrethrum* and *Senecio* occurring among the rest. An invaluable plant in this connection is *Santolium incana nana*, which in its cushioned tufts is quite unique. The pretty, ever-flowering *Erodiums*, silvery and otherwise, are here too, while such unique subjects as *Euonymus radicans kewensis*, *Pelargonium endlicherianum* and *Polygonum vaccinifolium* are receiving the attention they merit. Among choice shrubs, *Carpenteria californica*, *Fremontia californica* and *Fabiana*

imbricata were noted in quantity; while extensive accommodation exists for the best *Water Lilies*, which are already installed in considerable force. In short, it is a nursery destined to meet the requirements of all interested in hardy plant gardening, be the direction what it may.

The shop and offices of the firm are situated at 10, The Arcade, Liverpool Street, London, E.C., where exhibits of seasonable flowers are to be seen daily. Bulbs of all kinds are also well displayed just now, and purchasers can rest assured that every endeavour will be made to give satisfaction.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PRIMROSE PLANTS FOR INSPECTION (I. Barron).—The plants are not affected by any disease, but appear to us to have been left too long in the same place. The stem of most *Primroses* elongates, and new roots are annually produced just below the leaf rosettes. It is important that the plants should be placed in such a position that they may push their roots into the soil as quickly as possible.

HERBACEOUS PLANTS FOR SANDY SOIL (J. H.).—Providing your ground has been fairly well manured, you ought not to find any difficulty in growing a general collection of herbaceous plants. The following subjects will act as a guide to the kinds of plants to choose: *Delphiniums* in variety, *Phlox* in variety, *Sunflowers*, *Asters*, *Salvia nervosa*, *Lychnis chalcidonica*, *Monarda didyma*, *Gypsophila paniculata*, *Galega officinalis*, *Pentstemon*, *Snappedragons*, *Lilium candidum*, *Papaver orientale*, *Veronics* in variety, *Campanula persicifolia*, *Saxifraga cordifolia*, *Statice Limonium*, *Hollyhocks*, *German Irises*, *Saponaria officinalis flore pleno* and *Chrysanthemum maximum* varieties.

LAYING OUT A GARDEN (Rock).—We endeavour to assist our readers as far as is possible with advice and other matters, but giving garden designs—which, as a rule, would only suit individual cases—is beyond our scope. Your letter has two references to a pond, though your sketch merely shows a ditch 2 feet wide and 1 foot deep. If this shallow ditch is habitually water charged, it would affect the surrounding land, and of necessity the planting would have to be consistent therewith. In such cases much hangs on a very little, and we think your better course would be to send us a more complete sketch of the ground, indicate the position of the pond, and give fuller particulars as to the ditch and general surroundings. We may then be able to assist you.

HERBACEOUS PLANTS FAILING (F. A.).—Doubtless in every garden, or locality, you would find a few instances of plants not doing quite so well as the majority. Those not having grown luxuriously in your present garden are instances in point, and may be accounted for thus. The *Anemone* prefers a rather shaded spot and deep sandy loam. *Snappedragons* are most happy in light sandy, or stony, and poor soils. The *Flags*—*Irises* we presume you mean—are usually content in light or heavy soils, if away from trees and no wireworm is present in the soil. The *Epimedium* is a lover of sandy peat and loam and a cool-rooting medium. This plant is also at home in light loamy soils and shade. *Montbretias* prefer rich loamy soils, and are best when annually lifted and rested, taking them up in October and replanting singly in well-prepared ground in March or April. Success, however, has not to do with soils alone, and often the planting or the planter is at fault. For example, *Irises* or *Paeonies* are often planted in big clumps intact, when they should be divided freely. In the case of the *Iris*, 4 inches or 5 inches of the current year's rhizome (rootstock) and the growth is ample, all back sections of the rhizome being useless. By planting half-a-dozen or a dozen of these a few inches asunder, a good group would be formed, and the principle is worthy

of general adoption. Take care that you work the soil of your new garden as deeply as possible, and add light road sweepings and manure freely to improve the staple.

EREMURUS FAILING (*A. M., Ambleside*).—If you are sure that wireworm is not at the root of the trouble, it is highly probable that some ground fungus may be at work. In the seedling stage, and in frames, not a few things damp off wholesale; but we presume your plants have long since passed that stage. In all the circumstances, we are inclined to regard the trouble as of a fungoid nature and one which, in all probability, will be best remedied by a slight application of lime to the soil and to the parts affected. Are you sure that the plants are buried deep enough in the earth? since the Eremuri build their crowns one above the other, and so presently lift themselves out of the soil, and the roots emerging from the base of the crowns get out of touch with support. So many things that predispose to failure are frequently overlooked or unknown. If, on further observation, the fungus theory is supported, your better plan will be to lift and replant them in a fresh site in early October. The crowns should then be thoroughly cleansed by washing.

TREES AND SHRUBS.

PRIVET HEDGE (*Dolphin*).—You had better leave your Privet hedge alone until next spring as regards severe pruning, then you may cut it back as severely as you like. April is a good time. The Willow hedge you mention may be pruned at once if you wish.

BIRCH LEAVES (*X.*).—There is no fungus present to account for the dying of the Birch foliage. It is possible that the trouble is due, as you suggest, to the roots getting into too wet a substratum. A water-logged soil causes suffocation of the roots, and this reduces the amount of the supply of water to the foliage. The water supply might well be sufficient for the demand when the leaves first expand, and prove insufficient when they had reached a greater size and increased in number. 2. The Pears are attacked by the fungus *Fusicladium pyrium*. Adopt the measures we recommend in reply to "J. S." on this page. 3. As to the non-fruiting of the trees, is it certain that the pruning is carried out on the right lines?

SHRUBS FOR BANK FACING WEST (*J. H.*).—The following kinds are likely to prove satisfactory in the position you describe. All may be kept to within 4 feet or 5 feet in height: *Escallonia philippiana*, *Daphne Mezereum*, *Prunus japonica flore pleno*, *P. nana*, *Philadelphus Lemoinei* and variety *erectus*, *P. microphyllus*, *Olearia macrodonta*, *Cotoneaster thymifolia*, *C. horizontalis*, *Spiraea japonica* and variety *Anthony Waterer*, *Tree Ivies* in variety, *Tamarix pentandra*, *Berberis Aquifolium*, *Hypericum patulum* variety *Heeryi*, *H. moserianum*, *H. calycinum*, *H. androsarum*, *Cistus monspeliensis*, *C. ladaniferus*, *C. villosus*, *Helianthemum fornosum*, *Diervilla Eva Rathke*, *Phillyrea decora*, *Erica vagans*, *E. mediterranea* and variety *hybrida*, *Daboecia polifolia*, *Cytisus praecox*, *C. scoparius sulphureus*, *C. purpureus*, *Olearia Haastii*, *Genista hispanica* and any of the autumn-flowering *Ceanothuses*. The border should be trenched before planting.

ROSE GARDEN.

ROSES AND PEATY SOIL (*Rev. C. G. O. B.*).—We thank you for your letter re Mrs. Edward Mawley, and it is most interesting to learn from you that you have been so successful in the culture of this Rose. Undoubtedly many Tea and Hybrid Tea Roses revel in a peaty soil, providing they are well supplied with liquids in the growing season. Laurent Carle is a fine Rose in any soil, and we are glad you have found it good in your light soil. As regards Mile. Jeanne Philippe, this Rose is not nearly so much grown as it should be. It is a beautiful colour and a good grower. It was raised by Godard and sent out in 1899.

ROSE FOLIAGE BLIGHTED (*E. B.*).—We do not think any pest has attacked the foliage; but the shrivelled appearance is either due to cold, frosty winds, or the plants have been sprayed with some insecticide that has been too strong for them. American Pillar is evidently a hybrid between the multifloras and wichuraianas, for it possesses the glossy foliage of the latter and also some of its creeping tendencies. It is a grand climber, and its flowering period is early July in an ordinary year. The best blush rambler to flower with Hiawatha and Dorothy Perkins is Lady Godiva. Simplicity is a very good bedding Rose, but not quite so free in flowering as Irish Beauty.

SELECTION OF ROSES (*E. H. R.*).—A good dark red to grow as a standard would be Chateau de Clos Vougeot. For a reddish yellow you could not do better than select Duchess of Wellington. For a pale pink sort with pointed buds, Pharisar should please you, and a good white would be Mrs. Herbert Stevens. Comparing the value of Frau Karl Bruschki with Molly Sharma Crawford for garden decoration, we should certainly favour the former, as it produces its blooms erect. Although it is such a strong grower this, however, may be overcome by transplanting the bushes each year and pruning back rather hard. Molly Sharma Crawford is a very fine white, but has a tendency to droop.

PREPARING ROSE-BEDS (*P. J. Wood*).—We think your plan of procedure will be in the main quite all right; but instead of giving one-fourth of spent Hops to the surface, we would advise a dressing of gritty material, such as road scrapings from gravel roads, or better still, some burnt clay. The best plan to adopt to give the soil lime would be to apply it in the form of chalk at the rate of about two pounds per square yard. The chalk should be broken up into fairly small lumps. If you added some

as you trenched the soil, this would also be an advantage. We presume you intend to add some good farmyard manure to the lower soil as you trench it. This we consider very essential; and as you plant each Rose we would advise giving a handful of bone-flour just before filling in the top soil.

EXHIBITION ROSES FOR MANUFACTURING TOWN (*Exhibit*).—Unless you grow the Roses for the spring shows, we fear you would find it difficult to produce Roses under glass for the summer exhibitions. We advise you to plant the Roses outdoors, and then to erect over them a temporary structure of wood, upon which you could put light waterproof canvas to ward off excessive rains. The plants could then receive plenty of air, which they require, and you would have them more under control against the weather vagaries. You could still grow them in pots if you wish, but the pots should be plunged in soil up to the rim. There must, however, be no glass covering, or, if you do have this, let the sides and ends of the structure be open, that is, assuming you want to grow for the summer shows. Twenty-five good show kinds for your purpose would be Captain Hayward, Caroline Testout, Florence Pemberton, Frau Karl Bruschki, Hugh Dickson, Lady Ashdown, Melaine Soupert, Marquise Litta, Mrs. John Laing, Mrs. T. Roosevelt, Suzanne M. Rodocanachi, Ulrich Bruner, Countess of Shaftesbury, Dr. O'Donel Browne, George C. Waud, Gladys Harkness, Gloire de C. Guinoisseau, John Cuff, Jonkheer J. L. Mock, Lady A. Stanley, Lady Greenall, Mabel Drew, Mme. Maurice de Luze, Margaret and Mrs. A. E. Coxhead.

FRUIT GARDEN.

SPUR-PRUNING PEACH TREE SHOOTS (*Y. Z.*).—Pinch to within two leaves of the base all present growths, and subsequent ones also, the idea being to strengthen the basal buds of the shoots and compel the formation of fruit-buds.

GRAPES INFESTED WITH MEALY BUG (*J. W.*).—The only safe thing you can do to rid your Grapes of the pest is to syringe each bunch with clean rain-water. You will require to use considerable force in syringing to dislodge the whole. By using clean rain-water there will be no sediment left on the Grapes and no harm done, as they will be fit for dessert as soon as dry.

BOOK ON FRUIT GROWING (*E. G.*).—You cannot do better than order a copy of "Fruit Growing for Beginners," which will be published from this office in the course of a week or two. The price is 1s. net. It deals in a simple manner with the cultivation of all kinds of hardy fruit, and you will find the numerous illustrations very helpful.

PEARS (*J. S.*).—The Pears owe their roughness and splitting to the attack of the Pear scab fungus, *Fusicladium pyrium*. The leaves are also attacked and are being devoured by caterpillars. The best treatment for the former evil is to spray with Bordeaux mixture as soon as the petals drop, and for the latter with lead arsenate. Woolly aphid rarely attacks Pears. Some local condition must be at the root of the trouble with the Pears, causing their fall. Is the water supply all right? Trees on walls sometimes suffer badly from dryness at the root, although the rainfall may be copious.

MISCELLANEOUS.

WEED-KILLER (*Puffin*).—All the concentrated weed-killers of our acquaintance are of a distinctly poisonous nature, alike to plant and animal life.

NAMES OF PLANTS.—*T. W. C., Taunton*.—1, *Aster Linosyris*; 2, *Antirrhinum Orotinum*; 3, *Veronica speciosa* variety *Eclatante*; 4, *Lathyrus* species.—*G. B., Dorset*.—*Tamarix gallica*.—*Lionel Ward*.—*Anelhusa sempervirens*.—*Ignoramus*.—1, *Sedum Ewersii*; 2, form of *Viola munbyana*; 3, *Dianthus Carthusianorum*; 4, *Astrantia major*; 5, *Campanula gargarica*; 6, a fungus (not in condition for identification); 7, *Fuchsia Miss Lucy Finnis*. If by Sun Roses *Cistus* is meant, they may be propagated by cuttings in the autumn, but seedlings always make the best plants.—*R. M.*—*Hypericum humifusum*.—*A. Midgley*.—1, *Tropaeolum speciosum*; 2, *Sedum album*; 3, *S. reflexum*.—*F. W. Thompson*.—1, *Coronopsis* species, cannot name without flowers; 2, *Lamium purpureum* (?); 3, *Sonchus oleraceus* (Sow Thistle); 4, *Solidago virgaurea* (Golden Rod); 5, *Lapsana communis*; 6, *Hibiscus sylvicus*; 7, *Hesperis matronalis* (Dame's Violet); 8, *Iberis umbellata* (Candytuft); 9, *Linaria bipartita*; 10, *Petunia*, garden variety; 11, *Oenothera amœna*; 12, *Saponaria calabrica*.

NAMES OF FRUIT.—*R. J. G. Read*.—*Souvenir du Congrès*.—*J. Corry, Dumfries*.—Apple Yorkshire Beauty.—*E. F. B., Eye*.—1, *Louise Borne* of Jersey, dessert, October; 2, *Dovené du Comice*, dessert, November and December. —*Captain M. B.*—*Pennington Seedling*.—*Fig*.—Pears: 1, *Nouvelle Fulvie*; 2, *Vicar of Winkfield*.—*Colonel D. Guernsey*.—Apple Marsel and Pear Emile d'Heyst. —*A. C. C.*—1, *Vicar of Winkfield*; 2, *Bergamotte E-peren*; 3, *St. Luke*; 4, *General Todleben*; 5, *Beurré Superfin*; 6, *Beurré Balthé Père*.—*Constant Reader*.—1, *Court Pendu Plat*; 2 and 4, *Old Hawthornden*; 3, *Braddick's Nonpareil*; 5, *Cox's Pomona*; 6, *The Queen*. Yes; send some each week. —*S. W., Westgate*.—1, *Beurré Superfin*; 2, *Emile d'Heyst*; 3, *Lane's Prince Albert*.—*Captain C. E. K.*—1, *Leathercat Russet*; 2, *Hambleton deux Ans*; 3, *Vicar of Winkfield*.—*W. B., Reading*.—1, *Beurré Clairgeau*; 2, *Beurré Hardy*; 3, *Mère du Ménage*; 4, *Lord Derby*.—*L. H.*—All the numbers were detached and mixed. It is a very unsatisfactory way of sending fruit with the numbers attached by pins.—*E. H., Sudbury*.—We think the Grape is Foster's Seedling, but the fruits were almost a mass of pulp when they reached us, so that it is impossible to say with certainty. Grapes should always be packed carefully.

SOCIETIES.

READING GARDENERS' ASSOCIATION.

The first meeting of this vigorous society for the autumn session took place in the Abbey Hall (kindly lent by Messrs. Sutton and Sons) on Monday, September 23, when Mr. F. G. Drew (chairman of committee) presided over a large assembly of members. The lecturer for the evening was Mr. W. Camm of The Gardens, Cliveden, Taplow. Mr. Camm's subject was "Common-sense in the Cultivation of the Apple," and in his opening remarks said that his system, or, as some might think it, lack of system in the cultivation of the Apple, because based on common-sense, was adopted by him some years ago when taking his first complete charge at Battle. He pointed out that the rule-of-thumb method of pruning lateral shoots to the orthodox two eyes had to give way to a system the practice of which was based on the natural habit of the tree, its method of fruit-bud production and its general environment. Before it was possible to decide as to the best system to apply to any particular tree, these points had to be observed. Mr. Camm exhibited shoots of different varieties of Apples, showing how in some varieties fruit-buds were produced freely on the current year's wood in a manner resembling the Peach; with others fruit-buds were formed chiefly on short, stubby spurs along the sides of the unshortened shoots of the previous year. He pointed out how any material cutting back of these shoots induced growth instead of fruit-bud formation. Shoots of other kinds typical of a number of our best Apples were also shown, where the fruit-buds were largely produced at the termination of short lateral growths. Any shortening of these removed the greater part of the crop. He was careful to point out that his method of pruning and thinning applied to developed trees, and not to trees in the adolescent stage, whose chief business it was to grow—not to produce fruit—with which more severe methods of pruning were necessary in order to form a framework on which the fruiting wood was to be borne. A question with reference to summer pruning elicited the answer that the lecturer had neither time for it nor any faith in the practice. It might answer a useful purpose on young trees in a warm, dry soil. On older trees and heavy land it was generally detrimental. A very pretty collection of single Dahlias (from seed) was staged by Mr. H. C. Loader, The Gardens, Erleigh Park, who also exhibited vases of magnificent Asters Sutton's Shell Pink. Ten new members were elected.

THE EDITOR'S TABLE.

A New Moræa from Messrs. Barr and Sons.—Messrs. Barr and Sons of King Street, Covent Garden, send flowers of a beautiful and interesting new Moræa, a flower resembling in form the Spanish Irises. Messrs. Barr write: "We think you will be interested in seeing the beautiful Moræa iridioides Johnsonii, of which we send you specimens herewith. The flowers have opened with us in our office, and differ considerably from *M. iridioides* in being larger, more solid and lasting much longer. In the case of *M. iridioides* the flowers are more fugitive. We have now had these flowers in our possession three or four days. This Moræa was obtained by Mrs. Richmond from Ceylon, where it was imported from South Africa some years ago, and has considerably improved under the Ceylon climate."

Addresses of Gardeners Wanted.—The Editor of the *Horticultural Directory*, 10, Essex Street, Strand, London, W.C., will be glad if head-gardeners will notify him of any change of proprietorship or address since last October.

Another Cup for Rock Plants.—The Council of the Royal Horticultural Society offer at their show on March 4 and 5, 1913 (subject to the general rules of the society and the special regulations indicated below), a silver cup, presented to them by Messrs. R. Wallace and Co., for the best exhibit by an amateur of alpine plants, including suitable bulbs and dwarf shrubs, in a space not exceeding 5 feet by 3 feet. The use of stone is not absolutely necessary, but the judges will be instructed to favour its correct use and the natural arrangement of the plants in connection therewith. The plants may be either in pots or lifted.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Double White-flowered Colchicum.—

This is still a rare plant, if it has not been always so in greater or less degree. Indeed, no great quantity is ever to be seen at one time, and the plant is quite alone among its fellows. The flowers are not entirely pure white, though the occasional tinge of flesh colour seen in the early days of their opening do not rob it of any of its value.

Albino Forms of Geranium robertianum.—

At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Bowles showed the two albino forms of *Geranium robertianum*, one with a red stem, the other with a green, which have maintained themselves for a long time in his garden. Almost all the plants of the latter form appear to be traceable to one or two sources, and the committee would be glad to hear of its occurrence in a wild state.

National Vegetable Society's Show.—

This show, held at Watford on Wednesday of last week, and a report of which appears on another page, was the best the society has held, and we are glad to know that it was visited in the evening by a large number of people. As the Earl of Clarendon stated when opening the show, few are aware of the high state to which the cultivation of vegetables has been brought in this country. That an exhibit of vegetables can be made attractive was well demonstrated by Mr. E. Beckett, V.M.H., who surpassed all his previous efforts with an exceedingly beautiful and comprehensive collection.

Adonis amurensis.—

We remind those who are desirous of making their sheltered rock gardens as attractive at as early a season as possible of the merits of *Adonis amurensis*. It frequently flowers with the Snowdrops, and has bright golden flowers with all the beauty of the Spring *Adonis*. One may sometimes have it in bloom in January, and its bright flowers are most acceptable in the sunnier, though few, winter days. It is at its best in February in Northern gardens. *A. amurensis* has several varieties, such as the double one and one with a green centre, but none is more desirable than the typical *A. amurensis*. It may still be planted with success.

A Beautiful Autumn Shrub.—

Disanthus cercidifolia is a native of Japan, and is a close ally of the *Hamamelis*, or *Witch Hazels*, though belonging botanically to an entirely different family. The growth and foliage are rather suggestive of a bush of the *Judas Tree* (*Cercis Siliquastrum*). It is a slender-growing, spreading shrub, reaching in its native country to a height of 8 feet to 10 feet. The cordate leaves are about three inches across, bluish green in summer and distinctly glaucous beneath. It is in autumn when the bushes are most attractive. They then assume a bronzy red

tint, which before the leaves fall changes to rich claret red.

A Beautiful Autumn Bed.—One of the most pleasing beds that we have seen this autumn was a large one filled with the golden-flowered *Calceolaria amplexicaulis*, with a groundwork and broad edging of *Mesembryanthemum cordifolium variegatum*. The pale yellow foliage of this low-growing plant contrasted well with the brilliant yellow flowers of the tall *Calceolarias*. Such a bed would, of course, be beautiful nearly the whole summer, but its fresh and pleasing appearance in the first week in October specially commended it.

The Snowy Mespilus Against Conifers.—When visiting the gardens at Aldenham House, Elstree, last week, we were particularly pleased with a beautiful tree of the *Snowy Mespilus*, *Amelanchier canadensis*. The foliage had taken on a brilliant red tint, and as the tree had been purposely planted in a bay of conifers, the effect was particularly good. When the tree was in flower in spring, the effect would doubtless be equally good, the sombre hue of the conifers making a fine contrast to the snowy blossoms. Those who are intending to plant trees this autumn should bear this question of contrast well in mind.

Crab Apple Veitch's Scarlet.—There are several hybrid Crabs in commerce, but the above is not so well known as its merits deserve. It was produced by crossing the Red Siberian Crab with Apple King of the Pippins, and the general characters are fairly intermediate. The fruits are highly ornamental, the skin being bright red, changing to a deep crimson on the side facing the sun. They have a somewhat pleasant flavour, and are not to be despised for culinary purposes, particularly where Crab Apple jelly is in demand. When grown as a standard, the tree produces a fine effect both in bloom and in fruit, but the best results are obtained by planting single specimens where its full beauty can be displayed.

Hollow Trees.—In most instances, says Mr. W. J. Bean in the current issue of the *Kew Bulletin*, decayed hollows in trees have their origin in snags left by branches broken off that have rotted back into the trunk because the new bark has not been able to grow over and seal up the wound. Branches removed by design, or broken off by wind or accident, should always be sawn off close to the trunk, and the sawn surface should then be coated over with ordinary coal-tar. If a snag or stump is left, the bark cannot grow over it; damp, fungoid parasites and decay sooner or later follow and gradually find their way towards and eventually into the trunk. Such is the most frequent beginning of cavities in the limbs and trunks of trees. The coating of tar renewed every two or three years makes the wound water-tight and fungus-proof, its object being to serve as a temporary bark until a new natural covering is formed.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Hardy Fuchsias.—I quite agree with your correspondent "H. P." page 486, issue September 28, respecting the use of hardy Fuchsias in the garden. They are not grown as extensively as they deserve. There are few kinds of plants more graceful in habit or more free-flowering, and few that require less attention when once planted. In town and suburban gardens, where border space is naturally restricted, Fuchsias should be grown, as they look charming in narrow beds. Some of the varieties are suitable for training on division fences intermixed with other kinds of wall plants. In the Isle of Wight and in Hampshire there are specimens to be seen trained on cottages and growing to a height of nearly twenty feet. In the Bournemouth Public Gardens there are many plants, not all of the true hardy varieties, grown in the borders and left out both winter and summer. They are cut down fairly low every year, and in the summer the branches are long and strong and bear flowers in profusion. Mr. J. B. Stevenson, the Corporation head-gardener, told me recently that he found the treatment to answer well, and the effect is certainly very charming. This district is sheltered, but to my knowledge the Fuchsia does remarkably well in the open borders well up in the Midlands.—G. G.

The Best Apples.—When reading through the article on "The Best Apples and How to Grow Them" in THE GARDEN for September 28, page 491, I was, in my ignorance, rather surprised to find the writer using the word or term "Reinette" to locate a certain type of Apple. Representatives of this class were given as King of Pippins, Cox's Orange Pippin, Russets, Blenheim Orange and Ribston Pippin. Until reading the above-mentioned article I had looked upon the word Reinette as meaning nothing definite as regards the Apple itself, but as being used only to make a name. My source of information is Dr. Hogg's Fruit Manual, and for the sake of those readers who do not see this work and to arouse friendly interest in this part of Apple nomenclature I will quote the definition of the word Reinette from the Manual: "Thomas Fuller, the eminent historian and divine, says, 'When a pepin is planted (i.e., grafted) on a pepin stock, the fruit growing thence is called a Renate.' This, I think, is the origin of the word, Reinette being derived from *Renatus*—renewed or reproduced. A Reinette is therefore a grafted Apple, and a Pippin is a seedling." I should be pleased to see some further notes regarding this word Reinette, and to learn whether some definite rule has been formed regarding its use for classifying Apples.—A. T. C.

Roses with Bad Habits.—In an interesting note in THE GARDEN for September 21, page 474, on this important subject, I am glad to notice that "G. T. W." supports me in my endeavour to uphold General Macarthur both as a mildew-resister and as an otherwise ideal garden Rose. Curiously enough, "C. T.," on the same page, while absolving the variety from a predilection to mildew, complains of its shy-blooming qualities. Here it is one of the freest Roses in the garden, and even on September 28 there were dozens of fine blooms, besides quantities of buds in various stages, on the plants, twenty-five in number, growing in a large circular bed in the garden.

This bed is quartered with Liberty, Mme. Ravary, M. Paul Lede and General Macarthur. All have done splendidly, but the last-named by far the best. Mrs. Sharman Crawford is certainly very prone to the attacks of mildew. This season Killarney has been almost free from this trouble, and so has General Jacqueminot; but Margaret Dickson, as usual, is very badly attacked. Lyon Rose with us has but one fault—its drooping habit. It flowers abundantly, and usually gives very fine colour, but, as with others, varies in this latter respect. After reading "C. T.'s" note I closely examined Una, and can find no trace of mildew on it. It seems conclusive that climate, soil and surroundings have much to do with the behaviour of Roses in general.—C. B., *Lindilghow*.

Rock Garden Plants that Flower in Early Autumn.—*Silene Schafta* is one of the plants which should be added to the brief list given by Mr. E. H. Jenkins in his valuable and suggestive article under the above heading on page 502, issue October 5. It is simply indispensable, and

MR. EDWARD MAWLEY, V.M.H., HON. SECRETARY OF THE NATIONAL ROSE SOCIETY.

is yet in bloom in early October. *Tanica Saxifraga* and *T. olympica* are equally invaluable, and are still in bloom. *Origanum hybridum* is also in flower, and has been for a long time. It is most pleasing with its glaucous leaves and Hop-like heads of little flowers. *Anthemis cupaniana* makes a second bloom at this season, and is fine over a wall or on rockwork of some size. The old *Viola cornuta* and its several varieties are almost continuous blooming in summer and autumn. The old double *Helianthemum amabile*, commonly known as Mrs. C. Earle, is giving more or less bloom all the autumn; the little *Astrantia minor* and *gracilis* are good for autumn flower; and several of the *Erodiums*, such as *macradenum*, *pelargonifolium* and *cheilanthifolium*, are excellent. Late *Ericas* or Heaths and the forms of the common *Calluna vulgaris* are beyond praise for autumn bloom, and the *Menziesias* give flower as well. *Phuopsis* or *Crucianella stylosa*, though unpleasantly odorous at nights and in wet weather, is very useful,

and I find that *Cytisus schipkaensis* gives a succession of flowers from June until October here. *Ethionemas grandiflorum* and *persicum* still give bloom all the autumn, and *Geranium lancastricense* is rarely out of flower.—S. ARNOTT, *Dumfries*.

The Twelve Best Climbing Roses.—"G. B. W.'s" article on these in your issue of September 21, page 475, ends with the hope that his remarks on this interesting subject may call forth others. I feel that I am (or must be, in his opinion, at any rate) somewhat handicapped, inasmuch as I cannot thank heaven that I am not a rosarian, and must even plead guilty to that apparently greater sin of having once been (if I am not now) an exhibitor. Situated, therefore, as I find myself, it would be presumptuous to think that I can possibly improve on his list of the twelve best climbing Roses. I will only suggest that my list might be helpful if anyone wants more than twelve, or if he has any of those unaccountable prejudices that make or mar the taste of rosarians and exhibitors, and that will make him hesitate before ordering any one of "G. B. W.'s" dozen. Having said so much, let me hasten to congratulate "G. B. W." on his list. It is a real good dozen, but it reads a little curiously having regard to his conditions. They were (1) fragrance and (2) continuity of bloom. Six out of the twelve fail to pass the first test, and four out of the twelve fail with regard to the second. It is possible to compile a list of twelve climbing Roses that will have fragrance and continuity of bloom—that is to say, will flower more than once; but they might be found to fail in another requisite of a climbing Rose, namely, vigour. *Lina Schmidt Michel*, *Johanna Sebus* and *Trier* are cases in point. They are all in flower with me as I write, and are fragrant, particularly *Johanna Sebus*, which has a fragrance that few Roses can equal; but they are pillar Roses, and will not, as a rule, exceed 10 feet, *Trier* even less than that. Warned by "G. B. W.'s" example, I will not set down definitions or "characteristics" that the Roses cannot comply with, neither will I endeavour to place them in order of merit—that savours too much of the exhibition; but just in plain alphabetical order I submit the names of twelve climbing Roses: *American Pillar*, *Ard's Rover*, *Blush Rambler*, *Climbing Caroline Testout*, *Climbing Souvenir de Pierre Notting*, *Evangeline*, *Hjawatha*, *Lady Godiva*, *Mme. Alfred Carrière*, *Sarah Bernhardt*, *Tausendschön* and *Tea Rambler*. Of this list five will be found in "G. B. W.'s" selection, so nothing further need be said of them. Of the remaining seven two are new Roses, but I can recommend both of them. *Sarah Bernhardt* I have known for three years, and the more I see of it the better I like it. I have had three distinct crops on my plants this year. It is undoubtedly the best climber of its colour—a scarlet crimson that does not blue with age. The climbing sport of *Souvenir de Pierre Notting* speaks for itself. I doubt if there is a freer-flowering yellow than the type, and the sport seems to give us both larger and better flowers, and promises to be a good grower. On the ground of fragrance and continuous flowering, and I think I may add vigour of growth, I suggest List 1 beats List 2 in nearly every case; but, after all, I do not for one moment expect "G. B. W." to think so—*De gustibus non disputandum*—and he has a perfect right to his opinion. I should be much obliged to him if he will tell me where I can get *Marie Bret*, his No. 3, and what he thinks of my suggestions.—HERBERT E. MOLYNEUX.

Rose Psyche as a Pillar variety.—This Rose is a good example of a pillar Rose as distinct from a rambler Rose. It does not make long, rampant growths, as ramblers usually do, but will clothe a pillar splendidly up to 7 feet or 8 feet, the latter being the height of the support shown in the illustration. It is a vigorous Rose, with clean, glossy foliage and pale rosy pink flowers. A strong point in its favour is its ability to withstand mildew.—C. T., *Highgate*.

A Giant Groundsel.—Of several species of *Senecio* introduced from China during the present century, the one named *Senecio Clivorum* is the most popular. Being unusually vigorous and quite a giant in growth, it is not suitable for a small border. Rather should *S. Clivorum* be planted in the pleasure grounds, in masses by the lakeside, and in open places by the side of woodland walks. Wherever planted, good cultivation is necessary to obtain the plants in true character. The soil must be deep, moist and rich. Such conditions will result in *Senecio Clivorum* with inflorescences 4 feet in height and a mass of striking, heart-shaped leaves, each one exceeding a foot across. The flowers are golden yellow in colour, the flowering season August and September. When growing under favourable conditions the seeds fall, and by spring there are crowds of small plants requiring attention surrounding the parent rootstocks. Division of the roots or crowns in late October or March also forms a ready means of propagation.—A. O.

Greenhouse Plants for Winter Flowers.—Now and during the next few weeks is the time when one has to consider what to pot for flowering during winter or early spring. *Schizanthus* is one of the prettiest plants, of most elegant growth, and no plant is better adapted for a cool or intermediate greenhouse. Potted now into 5-inch pots in good, rich, sandy loam, they will flower early in the year. Plants of the mixed hybrids provide quite a variety of colour, most of the flowers being copiously spotted. Two other splendid plants which flower most freely and give a beautiful tone to the greenhouse and conservatory are *Primula hybrida* and the small, free-flowering variety *P. stellata*. These plants, potted into 3½-inch or 4-inch pots in a compost of three parts loam to one of well-decayed stable manure, adding a liberal supply of sand or finely-ground old mortar, will soon make fine specimens. As soon as the pots are full of roots, they should be moved on into 6-inch pots, using a similar compost to that previously mentioned.—J. L. E.

FORTHCOMING EVENTS.

October 14.—United Horticultural Benefit and Provident Society's Committee Meeting.

October 16.—North of England Horticultural Society's Meeting at Leeds. Lecture by the Rev. J. B. Hall on "Apple Culture." Wargrave and District Gardeners' Association's Meeting.

WORKERS AMONG THE FLOWERS.

MR. EDWARD MAWLEY, V.M.H.

IT would be exceedingly difficult to find in the world of horticulture, and particularly that section specially interested in Roses, a man who is more highly esteemed or more widely respected than Mr. Edward Mawley, V.M.H., the hon. secretary of the National Rose Society. For nearly forty years Mr. Mawley

ROSE PSYCHE AS A PILLAR IN A NORTH LONDON GARDEN.

has taken an active interest in the Queen of Flowers. It was at Croydon that he first commenced to grow Roses, somewhere about the year 1875 and in 1877 he became co-hon. secretary of the National Rose Society with the late Rev. H. H. D'ombrain. On the death of that esteemed rosarian in 1905 Mr. Mawley took over the full duties of hon. secretary, a position he has admirably filled ever since. From the commencement of his Rose-growing career at Croydon until he left there for Berkhamsted in 1885 he never had more than 400 plants, yet so keen was he in cultivating them

that he used to exhibit at all the National Rose Society's shows as well as at local and other exhibitions. At that time his prowess as an exhibitor, and, incidentally, the winner of first prizes, was so well known that his friends used to refer to him as the "champion of the light-weights."

When he moved to Berkhamsted, Mr. Mawley increased his collection of exhibition Roses to about two thousand bushes, and this enabled him to exhibit in larger classes with continued success.

In 1910 the National Rose Society bestowed upon him the Dean Hole Medal, which is awarded from time to time, as occasion may arise, to anyone who has rendered special service in forwarding the cultivation of the Rose.

But although Mr. Mawley has done such yeoman service for the Queen of Flowers, he has found time to enter the lists on behalf of the less universally beloved Dahlia, and, indeed, has been interested in that flower almost as long as in the Rose. For many years he acted as hon. treasurer for the National Dahlia Society, and on the death of his friend, Mr. Girdlestone, he became president of that society, a post he held until last year, when he resigned so that he could devote more time to the National Rose Society. Show Dahlias were his first favourites, but later he became more particularly interested in the Cactus section, and in recent years the single varieties have claimed his attention. He has been a most successful raiser of these, and secured certificates from the National Dahlia Society for a number of his seedlings.

In meteorological circles Mr. Mawley is almost, if not quite, as well known as he is among horticulturists. For over thirty years he was a member of the Council of the Royal Meteorological Society, for two years secretary to that Council, and on several occasions held the position of vice-president and ultimately became president, election to these positions being for two years. For over twenty years he acted as phenological recorder to the society, so that it will be readily seen that he has devoted no little time to a fascinating pursuit. His meteorological observatory, which he has maintained for nearly forty years, has always been, and still is, the best private one in the country. In 1904 the Council of the Royal Horticultural Society con-

ferred upon him the Victoria Medal of Horticulture in recognition of his services in the interests of gardening, an honour that was thoroughly deserved. As a private individual, as well as in his official capacities, Mr. Mawley is an exceedingly charming man, one who is ever ready to assist in any movement that is likely to benefit the flowers that he loves so fully, and we know that his numerous and world-wide friends will join us in the wish that he may long be spared to carry on his work, which to him, as to every enthusiast, is a labour of love.

PLANNING A ROSE GARDEN. A VISIT TO SOME IRISH ROSE GARDENS.

IN many a garden scheme it is found desirable that the Rose garden should be somewhat detached from other portions. That it should be so is not a bad general rule, because it is only for about three months in the year that it can be at its best, while the bare appearance in winter and the usual coating of manure do not make for beauty in the garden landscape. But if the Rose garden is in some retired place and fenced with a good Yew hedge, it need not be visited at a time when there is no display of bloom, and yet it has the shelter that is always desirable.

The plan shows such a garden of about a hundred feet square, with two equal divisions only separated by a wide grass path, with a central sundial. The paths are all of grass, for not only is the green of grass a better setting than the colour of gravel, but the grass is dry for walking upon during the summer months when the Roses are at their best. Four seats on paved platforms are notched into the Yew hedge, and four of the beds, two and two on either side as seen from the seats, have a central ornament on a stone-paved base. These may be ornamental vases, with tops rather than for plants, or, perhaps better, suitable figures in stone or lead.

The Roses, as shown on half the plan of the garden, are chosen so as to make a good effect of colour. On each side the four angle beds have kinds with deep red bloom, lighter coloured as to the inward facing margin. The large, outer middle beds have a main planting of the fine Zephyrine Droughin, a Rose that, well known in France, has only of late found its place in English estimation. Among garden Roses it is indispensable. Free in growth, lovely in form and rosy red colour and of sweetest scent, it is a Rose for every garden. The two beds nearest the sundial are of shades of pink, planted with Lady Ashtown and Caroline Testout, two of the best Roses for bedding purposes. The four square beds with the central ornament are of Roses nearly white, flushed and shaded with tender pink. The whole of the beds have an irregular edging, about eighteen inches wide, of *Stachys lanata*. This edging serves not only to enhance the beauty of the various red and pink colourings, but to fill empty space and to emphasise the lines of the design.

G. JERYLL.

FOR the National Rose Society to hold its provincial exhibition this year at Belfast was a happy move. Being termed "National," the society must justify its claim to the title by including Ireland within its venue, and after experiencing the easiness of the journey, the cordial welcome accorded and the excellence of the management of the exhibition, one confidently anticipates that it will not be long before the National Rose Society pays its second visit to Ireland. But it was a happy move in another respect; it enabled

done more to increase the number of Hybrid Teas now under cultivation, especially the so-called "exhibition" varieties? To name but half-a-dozen—Bessie Brown, Dean Hole, Dr. O'Donel Browne, Florence Pemberton, Mildred Grant and William Shean. What would be the position of the grower of specimen blooms if he attempted to compete without having them in his collection? And added to these, the cultivator of decorative Roses, which are now so popular, would surely feel the loss of Killarney, Liberty and Betty, and the series of single Teas sent out by this firm. Therefore, in anticipation of seeing good novelties, we visited the fields of Roses at Newtownards, and we were not disappointed. Of the Roses new and already in commerce we saw many, and made a

note of the following: Mrs. Cornwallis West (1911), flowers large and globular, white ground, shaded rosy pink. The growth of the maiden plants was strong and stout, running up 4 feet to 5 feet high, with dark green, leathery foliage. Although the blooms on maiden plants were good, this variety will probably be best as a cut-back, and one thinks it will before long be among the best twenty-four. Lady Barham (1911) is another good one; coral pink, globular, growth stiff, erect, but not tall. Mabel Drew (1911).—The name, one surmises, is, in the opinion of the raiser, an indication of its merit; a back-row exhibition flower, creamy yellow. Another Rose that attracted us was Ferniehurst (1911), the colour difficult to describe, a sort of rose pink shaded copper.

But it was the seedlings and those Roses of the present year that gave us most interest, the first being George Dickson (1912), a vigorous grower as a maiden, with blooms of good shape, imbricated, an enlarged Charles Lefebvre, reminding us

of W. E. Lippiatt and Victor Hugo. H. V. Machin was another grand red, brighter and perhaps finer in flower than the previous one. The blooms were carried erect on short, stiff stems, but the habit apparently was not so vigorous as might be desired. Irish Flame, like H. V. Machin, has already been before the public, and on account of its distinctive colouring will be popular for decorative purposes. In addition to these there were some attractive seedlings of the Rayon d'Or type. But the one that in our opinion stood out above all others was Mrs. S. T. Wright, a seedling of great promise, blooms of medium size, colour deep yellow, almost orange, high-pointed centre, growth vigorous and branching.

PLAN OF A ROSE GARDEN, ARRANGED WITH A VIEW TO COLOUR EFFECT. THE TOP HALF SHOULD BE PLANTED AS INDICATED FOR THE LOWER PORTION.

the English contingent to view at the same time the three chief centres of Roses in Ireland—Messrs. Alex. Dickson and Sons of Newtownards, Messrs. Hugh Dickson of Belmont, and Messrs. S. McGredy and Son of Portadown—and the purport of this article is to give a few brief notes of a flying visit paid to each of them.

Newtownards.—Messrs. Alex. Dickson and Sons were the pioneers in the Emerald Isle in raising new Roses. This firm has so enriched our gardens with new varieties that the term "Dickson's Roses" is only another way—a shorter way—of designating the Roses distributed by them. Apart from the Rose-growers of Lyons, has any firm

Belmont.—As all Rosarians are aware, Messrs. Hugh Dickson of Belmont is another firm that has given much attention to the raising of seedling Roses. The brothers, a few years ago, made it their especial work to introduce deep red and crimson into the colour of the Hybrid Teas, J. B. Clark, Hugh Dickson and Leslie Holland being some of their results, and now we have in King George V. (1912) the darkest of all the red Hybrid Teas; colour a rich velvety crimson like Charles Lefévre, globular in shape, growth on maidens very vigorous.

But in addition to reds, this firm is producing good salmons of the Lyon Rose type. Mrs. Sam Ross (1912) is one of these. The flowers are light chamois yellow, blooms large, full and sweetly perfumed; habit free-flowering, branching, and apparently of good constitution. A characteristic of the large number of seedlings on trial is their size and depth of petal. Of those introduced to public notice, Colleen will probably be one of the largest Roses. It was exhibited at the National Rose Society's show at Belfast this year. In colour it is not unlike Rose Her Majesty, but with high-pointed centre, petals thick, very full, vigorous growth. But an even larger and finer Rose is yet to come, a magnificent lemon-coloured Frau Karl Druschki, apparently the biggest of all Roses yet raised, strong in growth and very free-flowering. Another noticeable Rose, if one's notes are correct, was Mrs. Hugh Dickson, a Pernetiana, deep, dazzling, orange red. The name is indicative of its merit. We also noted some excellent yellows of the Melanie Soupert type, and more good reds as well, several of which will prove useful to the grower of specimen blooms; and one left the inspection of the seedlings of Messrs. Hugh Dickson with the feeling that before long the size of the exhibition boxes will have to be increased.

Portadown.—Messrs. S. McGredy and Son of Portadown have given us in the past some good Roses and, to be candid, some that have not fulfilled our expectations, or, shall we say, they do not feel at home in the English climate. However, we shall always be grateful to them for providing us with two such excellent Roses as (1)

Mrs. Alfred Tate, which in one's own garden has been admired by many visitors, and even now, at the end of September, is as good as, if not better than, at the height of the season; and (2) Mrs. Arthur Coxhead, a Rose which should be in everybody's garden, one of the sweetest-scented Roses we have, perfect in shape, and always in bloom right up to late October.

Each of the three eminent Irish raisers of seedlings is good in his special line, and if we observed size and substance in the seedlings of Messrs. Hugh Dickson, we found that the seedlings of Messrs. S. McGredy and Son were apparently pre-eminent in yellow shades of colour. Some were decidedly orange. When the

break of 35,000 seedlings came into view, the effect was startling. Here were developments of the Pernetiana and Lyon Rose types that were not even dreamt of five years ago, and M. Pernet-Ducher will have to look to his laurels. The first seedling that beckoned us, and we were bound to respond, was Mrs. C. F. Pearson, orange yellow, flushed with red, a distinct and striking colour, the form like A. R. Goodwin. Another was an excellent free-flowering decorative variety named Mrs. Vanderbilt, of a lovely orange salmon shade; also Lady Mary Ward, yellow orange. The raisers have a very high opinion of Colleen, an exhibition Rose of much vigour, large bloom, pointed centre, good shape, colour soft pink. But among such a

on slender stems and very free. As we moved up and down the rows inspecting in this group several hundred plants, every flower seemed perfect in shape and without a blemish, notwithstanding the damp season, which is somewhat surprising, because, unlike Frau Karl Druschki, the petals appeared thin in texture. If it does as well elsewhere as it does at home, it will be one of the best white Roses both for exhibition and the garden.

JOSEPH H. PEMBERTON.

A NEW TEA ROSE: LITTLE DORRIT.

LITTLE DORRIT is a beautiful Tea Rose with conical-shaped blooms that have aptly been described as a mingling of nasturtium red, apricot and cream, with a deeper shade of red on the outer petals. When shown by Messrs. George Paul and Son, Cheshunt, before the National Rose Society at the autumn show this year, it created something in the nature of a mild sensation among Rose experts, and by way of expressing a high opinion of its merits it was awarded the society's silver-gilt medal. The Royal Horticultural Society have since shown their appreciation of this novelty by granting an award of merit at the meeting held on September 24. It is a pretty Rose, with shapely buds and perfect bloom, as depicted in the illustration on this page.

ROSE LITTLE DORRIT, A NEW VARIETY AWARDED A SILVER-GILT MEDAL AT THE NATIONAL ROSE SOCIETY'S AUTUMN SHOW.

THE BEST ROSES FOR BEDDING.

EACH year it is becoming more difficult to make a selection of Roses for planting in beds. Naturally, one wishes to have the best, and oftentimes rarity or novelty is no obstacle, providing the desired colour and quality are attained. Moreover, in so many large gardens there are established beds of the leading sorts, or, rather, those that were considered best at the time of planting, and when new beds are contemplated, other varieties are sought after. It is generally admitted that catalogue descriptions do not assist one to arrive at a correct estimate of the value of the numerous Roses for the special

purpose of bedding or massing, so that an independent opinion by one who has grown all the varieties here mentioned may be serviceable to those readers who contemplate forming new beds this coming planting season. The list is rather a lengthy one, as I am quite aware that there is diversity of tastes. I can recommend all the varieties as being quite excellent for bedding purposes, and most of them produce their blooms upon erect stalks, which is such a desirable attribute in a Rose.

Rose-lovers are still in quest of a good scarlet and crimson, but we are grateful for what raisers have given us, as we know full well how difficult it is to obtain one's ideal. In golden yellows we are well supplied now by the addition of Rayon d'Or

number of attractive seedlings there were two unnamed ones that took our fancy most. The first was a full, globular, large exhibition flower of vigorous growth, long footstalk, erect, colour of Lady Alice Stanley and habit of Caroline Testout. The second was a sort of cream-coloured Frau Karl Druschki, a promising seedling in every respect.

Leaving the new seedlings, we were taken to see British Queen (see illustration on page 518), a white variety that the writer has seen at Portadown for two or three seasons. Messrs. McGredy have a large batch of it, and seen in the mass as we approached it from afar the sight was lovely, a veritable snowstorm. In habit it is bushy and branching, flowers pointed, globular, produced

and when we are able to procure Mrs. George Beckwith we shall indeed have a most marvellous colour in this section, one whose flowers are several shades deeper than Rayon d'Or. By the courtesy of Mr. George Beckwith I was able to compare the two quite recently. This new-comer is of the wonderful pernetiana group, which its raiser has evolved from Soleil d'Or. I have placed the varieties as near in order of merit as I could, and have indicated by (d), (m) and (t) their habit of growth, which signifies dwarf, medium and tall, and they are grouped approximately to colour.

White.—(t) British Queen, H.T.; (t) Frau Karl Druschki, H.P.; (m) Molly Sharman Crawford, T.; (t) Mrs. Herbert Stevens, T.; and (m) Yvonne Rabier, Polyantha.

Blush and Flesh Colour.—(t) Pharisaer, H.T.; (t) La Tosca, H.T.; (m) Prince de Bulgarie, H.T.; (m) Admiral Dewey, H.T.; (m) Princesse Mertchersky, H.T.; (m) Antoine Rivoire, H.T.; (m) Augustine Guinoisseau, H.T.; (t) G. Nabonnand, T.; and (m) Viscountess Folkestone, H.T.

Cream.—(m) Entente Cordiale, (m) Mrs. Harold Brocklebank, (t) Peace, (m) Mrs. D. McKee, (m) Mrs. A. Munt, (m) Mme. Pernet-Ducher and (t) Marie van Houtte.

Pale Yellow.—(m) Souvenir de Gustave Prat, H.T.; (m) Mme. Hoste, T.; (m) Alexander Hill Gray, T.; (m) Natalie Bottner, H.T.; (m) Paula, T.; (t) Miss A. de Rothschild, T.; (m) Mme. C. Guinoisseau, T.; (t) Gustave Regis, H.T.; and (d) Sulphurea, T.

Deep Yellow, Golden and Apricot.—(m) Rayon d'Or, pernetiana; (m) Sunburst, H.T.; (m) Duchess of Wellington, H.T.; (m) Mme. Ravary, H.T.; (m) Lady Hillingdon, T.; (d) Marquise de Sinety, H.T.; (m) Melody, H.T.; (m) Lady Greenall, H.T.; (m) Mrs. A. R. Waddell, H.T.; (d) Le Progrès, H.T.; (m) James Coey, H.T.; (m) Lady Roberts, T.; and (t) Lady Downe, H.T.

Buff and Mixed Yellowish and Cinnamon Shades.—(m) Arthur R. Goodwin, pernetiana; (m) Lyons Rose, pernetiana; (m) Melanie Soupert, H.T.; (d) Mrs. Aaron Ward, H.T.; (d) Paul Ledé, H.T.; (d) Aurore, China; (m) Comtesse du Cayla, China; and (m) Queen Nab, China.

Salmon Pink.—(m) Mme. Segond Weber, H.T.; (m) Mrs. Geo. Shawyer, H.T.; (m) Joseph Hill, H.T.; (m) Mrs. Alfred Tate, H.T.; (t) Betty, H.T.; (m) Lady Pirrie, H.T.; and (m) Mrs. W. Christie Miller, H.T.

Pink.—(m) Lady Ashtown, H.T.; (m) Mme. Leon Pain, H.T.; (m) Caroline Testout, H.T.; (t) Mme. Abel Chatenay, H.T.; (m) Mrs. E. G. Hill, H.T.; (m) Grand Duc de Luxembourg, H.T.; (d) Joseph Lowe, H.T.; (m) La France, H.T.; and (d) Maman Turbat, Polyantha.

Rose.—(m) Lady Alice Stanley, H.T.; (m) Mme. Jules Grolez, H.T.; (t) Gustav Grunerwald, H.T.; (t) Laurent Carle, H.T.; (m) Rose Queen, H.T.; (t) Kronprinzessin Cecilie, H.T.; (d) Mme. Maurice de Luze, H.T.; (m) Colonel Leclerc,

H.T.; (m) André Gamon, H.T.; (m) Lady Battersea, H.T.; (t) Mrs. Harvey Thomas, H.T.; (m) Countess of Shaftesbury, H.T.; (d) Camoens, H.T.; and (d) Orleans Rose, Polyantha.

Light Red.—(m) George C. Waud, H.T.; (m) Captain Hayward, H.P.; (d) Papa Gontier, T.; and (m) General Schablikine, T.

Medium Reds and Scarlets.—(t) General Macarthur, H.T.; (m) Lieutenant Chauré, H.T.; (m) Leslie Holland, H.T.; (d) Liberty, H.T.; (m) Richmond, H.T.; (m) Ecarlate, H.T.; (d) Jessie, Polyantha; (d) Leuchtfeur, China; (m) Mrs. E. Powell, H.T.; (m) Mrs. Walter Easlea, H.T.; (m) Commander Jules Gravereaux, H.P.; (m) President Vignet, H.T.; (m) Fabvier, China; and (d) Charlotte Klemm, China.

Dark Crimson and Maroon.—(m) Edward Mawley, H.T.; (m) Château de Clos Vougeot,

THE NEW ROSE EDWARD BOHANE THAT GAINED AN AWARD OF MERIT FROM THE ROYAL HORTICULTURAL SOCIETY ON SEPTEMBER 24.

H.T.; (d) Victor Hugo, H.P.; (m) Marquise de Salisbury, H.T.; and (d) Princesse de Sagan, T.

ROSE EDWARD BOHANE.

This has been an exceptional year for new Roses of really sterling merit, and one of the best of this season's novelties is Edward Bohane, illustrated above. The Royal Horticultural Society have shown their appreciation of this variety by granting an award of merit; it was also awarded a gold medal at the Royal Lancashire Show. This novelty is being sent out by Messrs. Alex. Dickson of Newtownards, but as the stock is limited, we are asked to announce that it will not be offered to the public until 1914. It belongs to the Hybrid Tea class, and carries bold flowers of deep cherry red hue.

CLIMBING ROSES WITH LARGE BLOOMS.

IT SHOULD be one of the last to disparage the beautiful Rambler Roses that have wrought such a marvellous change over the modern Rose garden, but there is such a thing as allowing these to usurp the place of the large-flowered climbers of which our collection is so rich.

Ramblers are all right upon arches and pergolas, but I think walls and fences can be better clothed with the strong-growing Teas, Hybrid Teas and Noisettes. What can be compared with a well-developed plant of Rêve d'Or clambering over a lofty south or west wall? It is a grand, fast-growing golden Rose which should be more frequently planted, but it is impatient of the pruning-shears; indeed, it is well almost to neglect it for a few years as far as pruning is concerned, and when it is pruned just shorten back the laterals a little and keep as much of the old wood as remains sound through the winter.

These glorious old Roses are a real joy to behold, and if we have the patience to wait for their development, they will richly reward us with a wealth of bloom.

There is a tendency at the present day to demand that the walls should be covered immediately, and we plant long-shooted, pot-grown plants very often, thinking this will help us to obtain our desire. But it is all a huge mistake. If the plants do attain a fair height, they are most miserably gaunt and ugly, and it is by far the better plan to commence with a sturdy plant from the open and prune it back to 2 feet the first year; then we may have during that summer quite a vigorous growth ready for a good crop of bloom the following year.

Of course, it is necessary to prepare well for these Roses. Give the border almost as much care as though we were planting a Grape Vine; that is, dig it deeply, fully 3 feet, but keep the subsoil in its own place and see that plenty of good farmyard manure is added, also some basic slag, which is a splendid reserve of food for some years. A handful or two of bone-flour also, given at the time of planting, will add a quality to the blooms that will be very gratifying.

There is no reason whatever why we should not have grand exhibition Roses from our walls, because we have everything in our favour, that is, thoroughly-ripened wood. We may have splendid blooms of Climbing Kaiserin Augusta Victoria far surpassing the original kind if we take the trouble to disbud a little. I am no advocate for nailing these Roses in so wonderfully exact. Rather would I allow some branches to fall away a bit, and to do this a few long spikes driven into the wall will serve to fasten such branches to. The walls appear less formal if this is done, and the growths are covered with bloom.

EXHIBITING ROSES IN BASKETS.

No one should miss an opportunity of planting Duchesse d'Auerstœdt. It is one of the best of the deep golden yellows, and is better for outside walls than Climbing Perle des Jardins, whose growths mildew so badly.

Dr. Rouges is another beautiful Rose, with quaint Cactus Dahlia-like blooms of lovely reddish colour with orange shading. It is a most profuse bloomer. Mme. Hector Leveillé and Mme. Charles Monnier are both very fine as yellowish kinds. A splendid red is Climbing Papa Gontier, which yields a great quantity of its very shapely buds that are always useful. Climbing Liberty and Climbing Richmond are both good reds. Florence Haswell Veitch will never fail to please, because not only has it a brilliant scarlet velvety shaded bloom, but it is so deliciously fragrant. These last three would be best planted against a moderately high wall, as they would not grow so rampantly as Dr. Rouges and Duchesse d'Auerstœdt.

A Rose that gives some superb blooms, though very sparsely, is E. Veyrat Hermanos. This should be planted where it can ramble away like Rêve d'Or, with similar treatment as regards pruning. The blooms are superb, reminding one of Comtesse de Nadaillac, but they need disbudding; in fact, it would pay to do this more frequently with these large-flowered kinds.

Billiard et Barré is a very rich yellow and a fine climber. It is much better used in this way than as a bedder. Belle Lyonnaise is another fine old sort; so also is Celine Forestier, which gives sheaves of its curious flat sulphur yellow flowers quite early in the season. A grand pink is Climbing Caroline Testout, perhaps rather shy, but good when it can ramble away, as it will. Climbing Captain Christy, though scentless, is worthy of a place; so also is Climbing Lady Ashtown if it is sprayed frequently to check its mildew tendency. Lady Waterlow is a superb variety, and should be in every garden; if not on a wall, then as a free bush.

I do not see why the Lyon Rose should not be used as a climber. I am planting it in this way and also as an espalier Rose, a form to which I imagine its somewhat erratic growths are peculiarly fitted. A favourite Rose of mine is Souvenir de Mme. Joseph Metral. Every bloom is as big as Mamie and of a delightful cerise colour, and it grows most freely. Noella Nabonnand is another beauty and as fragrant as it is beautiful, its huge semi-double flowers being quite gorgeous in effect.

I cannot name all that are good, but I just mention the foregoing, which if planted will enrich the garden very considerably, and a place should be found for them all if possible. Some truly beautiful effects are now and then seen in country gardens where some of the foregoing climbing Roses are allowed to cover coach-houses, tool-sheds and similar positions, for then they all contribute towards the beautifying of the place.

DANECROFT.

ONE of the most pleasing features of recent exhibitions of the National Rose Society has been seen in the well-contested classes for Roses—not on show-boards, but shown in a far less formal way, and that is in baskets. That Roses when so exhibited are infinitely more effective and natural no one will deny, and the Rose-loving public must feel that they owe a debt of gratitude to the Rev. J. H. Pemberton, president of the National Rose Society, who is responsible for having popularised this method of exhibiting the Queen of Flowers. Roses of many classes are amenable to this informal mode of showing,

NEW BREAKS IN ROSES.

THE history of the modern Rose is marked from time to time by the appearance of varieties which, constituting new breaks, reassert her supremacy in the garden. Varieties like Gloire de Dijon and Maréchal Niel will suggest themselves to all as among those which have influenced our best and latest yellow Roses, and Mrs. W. J. Grant is another instance of how much one variety can help the progress of the Rose. This fine Rose, like Mme. A. Chatenay, Caroline Testout and others, was the offspring of V. Verdier, and gave, in combination with La France, which was another break, many of our best autumnal bedding varieties. Neither do we forget Soleil d'Or, the hybrid from Persian Yellow, which has

A BASKET OF ROSE LYON EXHIBITED AT THE NATIONAL ROSE SOCIETY'S SUMMER SHOW IN LONDON.

the singles, such as Irish Elegance, associated with their own foliage, being particularly graceful so long as the blooms keep fresh. Some of the newer Roses with comparatively small flowers, notably the new race known as pernetianas, would be quite lost on the show-board, but are seen to the best advantage when shown in baskets.

In the accompanying illustration is seen a basket of the Lyon Rose, shown by Mr. Chaplin at the National Rose Society's Summer Show. The basket in question, although containing blooms of the finest quality, would have been even more effective if buds as well as expanded flowers had been shown, and this, we think, would more closely carry out the wishes that the Rev. J. H. Pemberton had in mind when advocating this admirable method of showing Roses.

introduced new features into our Hybrid Teas, giving us such varieties as Lyon, A. R. Goodwin and Mrs. A. R. Waddell, not to speak of those not yet offered, such as the superb Mme. E. Herriot, or the dainty Willowmere, or that much-improved Rayon d'Or which is to be called Mrs. G. Beckwith. The influence of the Austrian is already entering, too, into our climbers, and we find this in such sorts as Louis Barbier and Entente Cordiale (of Guillot).

But here the result has mainly been one of colour. With two classes of climbers now merging into one, the multiflora and wichuraiana hybrids, we have new effects in habit, foliage and size of bunches. All these improvements are largely derived from that complete break, Crimson Rambler, although the importance of Rosa wichuraiana must not be forgotten, and to the multifloras we also owe one of the most distinct additions to our gardens—the

baby ramblers. Of these, the most striking are Mrs. Cutbush, Jessie and Orleans Rose. In Maman Turbat and Yvonne Rabier we have promise of a corresponding race of baby wichuraianas of much novelty and beauty. In these cases it will be seen how often a new race originates from some startling novelty which arrests the attention of hybridists. At least, this is so with the more modern breaks. In the olden days the raisers of new Roses must have been men of imagination and intuition in no slight degree, for they had no Mendel's law to guide them. I have by me some old portraits which, deficient as they are, afford much cause for thought. These men struck some potent notes, though they were perhaps before their time, for there are yet upon the shelves some of their unworked themes, which should be developed.

The Roses which make history are, after all, not many, and there are some still which are waiting their turn. As an illustration let me go back to a favourite theme of mine, the Musks. These and the Noisettes, for the two are one, have been for a long period in the shade, but their day is nearly come. It is not for nothing that the National Rose Society gave this year at least three awards for novelties of Musk origin, varieties perhaps not in themselves of superlative merit, but significant of many possibilities, since herein lies the promise of autumn climbers. The chief work in this class has been done within the past few years, and yet lying at hand was the material from early days. My attention was first called to this class by some German novelties, Leonie Lamesch and others, which showed the qualities of the Noisette breed. The credit for these must be attributed to Mr. P. Lambert of Trier, one of the most original-minded rosarians we have. Rose-growers will recollect his perpetual climber Trier and his other Musk hybrids, half-climbers like Adrian Riverschon and Dr. Mittweg, and his dwarfs of a similar strain, Gustave Meyer, Meise and others. Mr. Pemberton has proved a worthy rival to Mr. Lambert, and with his Danae has certainly introduced into the climbing Musks what was largely lacking—colour; so the Germans will not have it all their own way. We have yet to eliminate tenderness from this race and to improve their floriferousness, although they flower well in the autumn already.

Another break which we should not fail to remark is Grüss an Teplitz, originating, I believe, partly from the Chinas, but also with the blood of Gloire des Rosomanes, ancestor of our crimson Hybrid Perpetuals. This is a most original break, and one proving how necessary it is to sometimes hark back to earlier types for novelty. Grüss an Teplitz has already justified its existence in giving us Hugh Dickson, the best red autumnal.

Much of the above reads like ancient history, but one feels that in these earlier developments we shall find guidance for the future.

Now that the hybrid bedding Roses are, as was the case with the Hybrid Perpetuals of an earlier period, reaching probably their highest point, it is needful to look for new points and features. Already the H.T.s and H.P.s are being combined, as in Frau Karl Druschki. Let us briefly see what we have yet to gain. Such qualities as texture of bloom, of petal, mildew proofness, hardiness and vigour, in combination with fragrance, leave a wide field to be yet covered. The large-flowered climbers have not yet reached the excellence of such few kinds as Mme. A. Carrière, nor is there yet a really first-rate red large-flowered kind. The evergreen foliage of the wichuraianas has yet to be distributed. Even the species might be searched for novelty and their fruits improved.

A WEEPING STANDARD OF ROSE ELISE ROBICHON IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

There is a new Hybrid Tea, Mrs. E. Powell, with glorious rosy red flowers. The wood is purple, the foliage almost black, no signs of mildew, hardy and vigorous, which illustrates how each additional quality enhances the value of the whole. Such qualities are to seek, for we must add them to even our best Roses. A Lyon Rose or a Rayon d'Or which did not drop its leaves would be a distinct advance. There are enough new wild kinds from Asia alone to afford work for a whole generation. To work with species is long and tedious, yet to secure even only one kind of such supreme loveliness as, say, sinica Anemone should prove a sufficient reward. GEORGE LAING PAUL.

ROSE ELISE ROBICHON AS A WEEPING STANDARD.

WEEPING standard Roses are becoming more and more popular in each succeeding year, and deservedly so, for it is beyond doubt one of the most graceful forms in which Roses may be grown. The specimen plant shown in the accompanying illustration is one of many as seen growing in the Royal Horticultural Society's Gardens at Wisley. In these gardens weeping standards are a great success, and constitute a most pleasing feature. Among the best of the varieties we noted in these gardens last June were François Guillot, Alexandre Pirault and Joseph Billard. The trees had all been grafted about four feet from the ground, and throughout June were literally clothed with bloom down to the soil-level.

COLOURED PLATE.

PLATE 1456.

ROSE DUCHESS OF WELLINGTON.

AMONG Roses of recent introduction, the variety shown in the accompanying coloured plate is destined to hold a prominent position. It is one of the many good Roses that the famous Irish firm, Messrs. Alex. Dickson and Sons, have given us, and was first put into commerce in 1909. It is pre-eminently a garden Rose, combining good habit with vigorous growth and freedom of flowering, and is not addicted to mildew so much as many other bedding Roses. In addition to flowering freely during the summer, it is particularly free in the autumn, when its rich colour is, in many instances, seen to even better advantage than earlier in the year. This colour is almost, if not quite, unique among Roses, and has endeared the variety to all who have seen it in good condition. Apart from its colour it has a delightful fragrance, a feature that is, alas! too often absent in present-day Roses. It is now possible to have a Rose garden of all yellow or shades of yellow Roses, should one so desire, now that we have, in addition to Duchess of Wellington, the brilliant

Rayon d'Or, James Coey, Arthur R. Goodwin, Sunburst, Lady Hillingdon, with the older Gustave Regis, Le Progrès and Mme. Ravary. We mention these to show to what extent the list of Roses with yellow-hued flowers has been enriched during recent years. But good as most of these are, they can only be regarded as the forerunners of a race of yellow Roses that will do much to revolutionise the cultivation of the Queen of Flowers, not only for the embellishment of our gardens, but for market purposes. The flowers from which the accompanying coloured plate was prepared were kindly supplied by Messrs. H. Merryweather and Sons, The Nurseries, Southwell, Notts.

“ROSE DUCHESS OF WELLINGTON.”

THE BEST ROSES FOR TABLE DECORATION.

I AM sure everyone will agree with me that, lovely as all flowers are for dinner-table decorations, Roses are really the favourites; one never tires of them. For one reason, there are so many varieties, and all varying in their form, size and beauty. Then their scent is so delicious that, however hot a room may become, no one will be overcome by their perfume, as is the case with so many other flowers. It is very difficult to say which are the best Roses for decoration, as some prefer large Roses and others single ones. Unfortunately, so many of the single Roses close up at night, Irish Elegance being an exception. To my mind nothing looks more exquisite than a dinner-table decorated with Irish Elegance, with a low silver bowl for the centre-piece and silver vases round, the lovely long-pointed, orange red buds and the fully open salmon-tinted flowers being brought out to their fullest perfection by the white table-cloth and the light of the candles. Mme. Abel Chatenay is a general favourite and always looks lovely; it is also such a graceful Rose that even when full blown it never looks heavy.

I think a great deal depends on the size and shape of a table what flowers should be used. I remember decorating a very long table with large blooms of Caroline Testout and long trails of Rose foliage from one end to the other; it sounds somewhat heavy, but the effect on the large table was most pleasing. Melanie Soupert is a lovely Rose if one can get it just in the bud, but it opens very quickly, and when full blown is not very pretty. I think a table of Richmond, arranged in white china vases with pale green foliage and long feathery trails of Asparagus Fern, is very effective. A lovely Rose for decoration is Joseph Hill, the stems being so very stiff and long; it also lasts a long time and looks well to the end. Sulphurea is a pretty little Rose with its own dark foliage, especially in the autumn when Roses are becoming scarce. Sinica Anemone, a large silvery pink single Rose, and one of the first to come out, is very striking. Dawn makes a very pretty table done in rather low bowls and with some other foliage, its own not being adaptable for decorative purposes. I am very fond of all the wichuraiana Roses.

Alberic Barbier, one of the earliest, mixed with Carmine Pillar, always looks well. François Juranville is also delightful with its lovely shell pink flowers, shining leaves and red stalks. Dorothy Perkins, everyone's favourite; Hiawatha, if you can get it when the flowers have just opened; and Lady Godiva, which is so easy to arrange with its pretty little clustered sprays of the palest pink flowers and bright green leaves, are all beautiful.

A dinner-table of all very pale-tinted Roses is charming if they blend well together, such as White Maman Cochet, Viscountess Folkestone, Safrano and Gustave Regis. Some of the new Roses seem especially adapted for tables, being small

and easy to arrange—Sunburst, which is lovely and lasts well; Mrs. Fred Straker, Lady Pirrie, Lyon, Mrs. Alfred Tate and Lady Hillingdon. Though the latter is an exquisite colour, the buds and the flowers are so very set and so much alike that it makes rather a stiff and somewhat disappointing table. I am not very fond of pure white Roses for a table; against the white cloth they look too cold and colourless, and have a very artificial look unless coloured candle-shades are used. Then the result is very good.

It is always very difficult to get just the right vases for the right flowers; tall, slender vases often look bare and unfinished, even when surrounded with sprays of foliage; yet if you have many low round vases, the result is often too squat and solid-looking. The centre-piece should never be too high, as it hides the view across the table. If one is the happy possessor of old silver decanter stands, what can be more lovely and effective

JUDGING NEW ROSES.

IT is generally agreed that the present system adopted by the National Rose Society in awarding its medals leaves much to be desired, but the problem is what can be substituted in its place. I am firmly convinced a trial ground is needed, and we shall not arrive at a just estimate of the value of a novelty until such a trial ground is an accomplished fact.

It has been suggested that a jury should be elected to visit the raisers' gardens and inspect the novelties; but seeing that such gardens are widely apart, this scheme does not commend itself to the practical man, and yet some arrangement of this sort is needed, and for this reason: If one can see a large quarter of any new Rose growing, one is able to form a just opinion of its merits better

AN EFFECTIVE ARRANGEMENT OF ROSE DOROTHY PERKINS AND ITS WHITE VARIETY ON THE ROSE PERGOLA AT KEW.

for the outside vases; also the pretty cut-glass jelly-glasses that our grandmothers prided themselves upon, and who would have deemed it desecration to have used them for flowers. Unfortunately, we do not all possess these old treasures.

J. B. LANGTON.

ROSE MRS. FRED STRAKER.

This delightful Hybrid Tea Rose is destined to become very popular, perhaps even to rival Mme. Abel Chatenay. The long and elegant buds finish beautifully, making a lovely coat-flower, and it is ideal for sprays. As a garden Rose it will be one of our very best, the growth being erect and vigorous, and its foliage, being bronzy green, contrasts well with its flowers. Moreover, one is not troubled by mildew, as this variety seems to be quite immune from this pest.

than from a dozen or two dozen selected specimens. British Queen was submitted to the judges at Belfast and passed over, whereas some of the judges who saw the fine array of it at Portadown would have given it a gold medal without hesitation, an honour that it has since gained. My opinion is that a sub-committee could well be appointed by the National Rose Society to visit the various raisers and make notes, which would be of great value when the Roses were brought before the judges at either of the society's shows. The sub-committee should be instructed to watch the behaviour of each Rose as a cut-back, for I am persuaded that many gold medals have been wrongly awarded to Roses that are good as maidens only. It is easy enough to get a fine big bloom from a maiden plant; but how is it going to behave when the amateur purchases it?

One of the loveliest Roses with me this year has been Mrs. Arthur Munt. Now I know this variety failed to obtain the gold medal, but it would most certainly have succeeded had the jury seen the Rose growing. Again, I venture to say the gold medal would not have been awarded to several varieties that did gain it, for a like reason.

I have an alternative suggestion to make, and that is that some gentleman should be asked to allow a trial of novelties to be made in his garden, say, for two years. Supposing our honoured secretary, Mr. Edward Mawley, would undertake such a trial, Berkhamsted would be easily reached by a committee of experts appointed by the society, and awards made on the spot, or, finally, when the Roses were put up at the show. Of course, it would be better still if the National Rose Society possessed its own trial ground, where all members could have access. Such a Rose garden under the charge of a thoroughly reliable and capable superintendent would be of untold value to the society, and would be, I feel sure, well patronised by the Rose-loving public, who would find in it an extra inducement to join the society. The augmented number of members would soon repay the society for the upkeep of the garden. We want such a garden not only for novelties, but also where one could see some of the good old Roses for comparison. Supposing a certain variety was thought to be too much alike another, this matter could be settled right away by comparison. This is a very fitting time to ventilate this subject, and I feel sure no one wishes this country to be rivalled by France and America, for both these nations possess trial gardens for Roses. W. EASLEA.

THE BEST AUTUMN ROSES.

EVEN to the present day June is often styled the month of Roses. It is true that we get a fairly good show of bloom during that month in favourable seasons, and used to have a greater proportion among the older varieties, but I venture to say we have quite as much right to claim September as a Rose month since the advent of the numerous and charming varieties of Hybrid Teas. There are a great number of these which appear at their best during autumn, and this is all the more noticeable because so many of our so-called summer bloomers are quite done with, and the majority of the Hybrid Perpetuals give few autumnal blooms, and then only one here and there. I must, however, make an exception in favour of Frau Karl Druschki, Victor Hugo, Ulrich Brunner and Mrs. R. G. Sharman Crawford from this section.

Such Teas and Hybrid Teas as G. Nabonnand, Peace, Betty, Mme. Ravary, Killarney, Theresa Bevan, Edu Meyer, Lady Ashtown, Lady Battersea, General Macarthur, Grüss an Teplitz and Mme. Antoine Mari—only to name a dozen as they

occur during writing—are among the freest and choicest of all Roses during the autumnal days. The cooler weather conditions would seem to suit this class of Rose far better than the brighter days of midsummer. Certainly they open in a firmer and most lasting way, while the autumn foliage of many is also much deeper in colour than when somewhat crippled by bright sunshine, which has a tendency to dry up these succulent and bronzy purple shaded growths, many of which are well worth growing in the autumn for the beauty of their foliage alone. Irish Elegance, G. Nabonnand, Mme. Ravary, Perle des Jardins, Joseph Hill and Grüss an Teplitz are half-a-dozen with

NEW ROSE BRITISH QUEEN, THAT GAINED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S AUTUMN SHOW.

particularly pleasing foliage, and not so prone to mildew as many.

A few of our best autumnals produce large, spreading trusses that are carried boldly, while each flower is upon so long a stem of its own as to allow of useful cutting without destroying a number of unopened buds upon the truss. La Tosca, Peace, Mme. Antoine Mari, Peggy, Molly Sharman Crawford, Corallina, Mme. Abel Chatenay, Mrs. A. R. Waddell, Edu Meyer, Lady Battersea, General Macarthur and Betty are twelve good examples of this.

To me it appears that the autumn Roses have a more pronounced perfume than those opening

so hastily in the summer, perhaps because the centres of the flowers, where the perfume seems to emanate from, has had a better opportunity to develop.

Uckfield.

A. P.

A FEW GOOD ROSES FOR MASSING IN BEDS.

DURING the past few years there has been a distinct advance—chiefly among the Hybrid Teas—of Roses well suited to this form of decoration. In my opinion, formed chiefly from our success with it at Gunnersbury House Gardens, Joseph Hill, the subject of the illustration on page 519 is one of the best. It is good at all seasons, both early and late. Just recently we have had some very fine flowers, and that, too, in large trusses without disbudding. (This form of culture is not countenanced here.) It is invariably good in colour—a salmon pink, shaded with yellow and ochre, outside of petal, coppery pink. In growth it is very vigorous, yet very sturdy; hence it stands the winds well and its hardihood is beyond any question. We find hard pruning to suit it admirably. I am somewhat surprised to think it is not better known. At the recent autumn Rose show of the National Rose Society it was rarely to be seen in any stand, yet it is one of the most attractive of all. Its rich bronzy, healthy foliage lends itself to this feature. Mildew gives it but little trouble. Of other Roses that thrive well here, Prince de Bulgarie is one of the best. It is somewhat in the way of the preceding, but with more variation in its colouring. Souvenir de President Carnot is excellent; nothing better in its colour. Both Richmond and Liberty are fine as crimsons. Sometimes one is best and sometimes the other. Antoine Rivoire has been perfectly lovely throughout this season; better than last year when so hot. Lyon Rose has also been better. I wish it did not shed its leaves so prematurely. Mme. Abel Chatenay has been most troublesome with mildew, yet it is almost indispensable in its colour. Kaiserin Augusta Victoria is not beaten yet in its purity of colour and freedom of flowering. Corallina is excellent, and quite immune from mildew with

us. La Tosca is a fine Rose, most robust and very free, with scarcely a trace of mildew upon its lustrous foliage. Souvenir de Pierre Notting is excellent as a pale yellow, better in dry weather than in wet. Last year it was fine. This makes a dozen varieties, all of which we find to do well with hard pruning. I should have added that ever popular Caroline Testout. Grüss an Teplitz, as a deep crimson scarlet, is fine, but with us it mildews badly, and the same applies to Frau Karl Druschki. The former we prune moderately and the latter scarcely at all, merely thinning out the weakly wood.

JAMES HUDSON, V.M.H.

Gunnersbury House Gardens, Acton.

NOTES ON NEWER ROSES.

(Continued from page 499.)

ALL Roses fall naturally into two sections (except from the botanist's point of view) and I will call them decorative and exhibition. These notes will be divided in the same way, with a further subdivision as regards the former into dwarfs and climbers, and as regards the latter into the still useful but almost worn-out sub-divisions of Hybrid Perpetuals, Hybrid Teas and Teas. As a new Rose is more important to the exhibitor, I will deal with exhibition Roses first, and endeavour to condense my notes thereon, so that they will all appear in the next four issues, and so perhaps may prove of service before all the blanks are filled up and the discards replaced from the nurseries—for it should be an annual practice for the exhibitor to run through his Roses, especially where his space is limited, and weed out such varieties as are no longer serviceable in the strongest sense of the word. By that I mean plants that do not give a good percentage of exhibition flowers per plant. Roses differ enormously in this respect, and I think one might almost say that, the older the variety, the greater the number of plants that will have to be grown to make sure of finding a good flower when you want one.

The discriminating exhibitor, with his carefully-thought-out list of, say, 200 varieties, scores heavily over his less careful rival, who may grow his Roses equally as well, but who is growing a number of plants that are good old names, but that seldom give him a flower that he can stage with advantage. Perhaps the National Rose Society might see its way clear to draw up an "ideal" list for the 200 plants man, giving not only the varieties, but the number of each that should be grown, having due regard to locality and other matters that would necessarily have to be considered.

EXHIBITION ROSES ONLY, 1909-12.

Hybrid Perpetuals.—These are very few and far between. Doubtless a few more might be discovered labelled as Hybrid Teas, but there are apparently only two that I need refer to under the head of Hybrid Perpetuals.

George Arends (Hinner, 1910).—A seedling with a lot of Frau Karl Druschki blood. It is rose pink in colour, of good habit of growth, but is not so good as Elizabeth, and is similar. It has more scent than that variety, but I do not think we want them both, and Elizabeth is more reliable.

Gloire de Chedane Guinoiseau (Guinoiseau, 1909).—This is a good Rose, and has been very largely exhibited this year. A good-coloured crimson, it has claims to be considered one of the best of its colour, and all exhibitors should grow it. It has the further advantage of having been three years in commerce, and so has reached normal prices—1s. to 1s. 6d. each. It has frequently this year been found winning the medal for the best Hybrid Perpetual in the show, and when a Rose does that pretty often, nothing more need be said. It lasts well when cut, and does not grow smaller in the exhibition box, as some of the reds will. Its percentage per plant is fairly high—considerably better than either Edward Mawley or Leslie Holland in this respect. Altogether I can recommend this Rose as worthy of a trial.

This is a meagre list of Hybrid Perpetuals for three years, but I can call to mind no others.

Southampton.

HERBERT E. MOLYNEUX.

(To be continued.)

THE GREENHOUSE.

WORK AMONG THE CHRYSANTHEMUMS.

DURING the whole of this month the plants will be developing their buds, and by the end of it cultivators will be able to judge as to the quality of the blooms of the various varieties that are being grown for exhibition and for forming conservatory and greenhouse groups. In order to have late, medium and early varieties at their best on a given date in November, it will be necessary to do a considerable amount of shifting of plants to and fro from one house to another, and even in different positions in the same house. There are also the questions of artificial heat, shading and feeding. All combine to aid in the production of perfect blooms. Many cultivators like to arrange their plants in groups directly they are

seen numerous white surface roots killed in a few hours owing to the too frequent application of nitrate of soda and given in too strong doses. If a teaspoonful of nitrate of soda be dissolved in a gallon of water, and one dose of this strength only be given to plants that are backward during the whole of October, it will be sufficient. The concentrated manures sold by horticultural sundriesmen should never be given stronger nor more frequently than is recommended by the vendors. I know that many inexperienced cultivators overdose their plants, thinking that they can develop a monster bloom from a tiny bud. Result—crippled root action and a badly-developed bloom. I have seen buds that never properly developed, owing to the plants bearing them having been fed too much. Clear soot-water made from old soot may be given occasionally.

Fire-heat and Ventilation.—A nice buoyant atmosphere should be maintained in the house. The colours are clearer and richer when the blooms open in a rather cool temperature and dry atmo-

AUTUMN BLOOMS OF ROSE JOSEPH HILL IN THE GARDENS AT GUNNERSBURY HOUSE, ACTON.

taken to the houses. This should be avoided, if possible, as the grouping together of many plants for a period of five or six weeks results in the loss of bottom leaves wholesale. In all cases it cannot be avoided, on account of lack of room, but where there is ample space it is much the best to put the plants in twos and threes in different parts; then the air can circulate freely through them, and their basal leaves are retained in a fresh condition until the blooms are three parts developed at least. The groups may be formed when the blooms are at this stage, and owing to the freshness of the leaves, the effect will be more pleasing.

Feeding.—This should be continued until the flowers are a little more than half developed. There is much art in the feeding of a plant. Some cultivators do more harm than good in the use of artificial manures. Nitrate of soda, sulphate of ammonia and similar stimulants which are of a strong nature must be used with great care, else many valuable roots will be killed. I have

sphere. A little night ventilation is essential, and more in the daytime when the weather is fine. In foggy weather have rather more heat in the pipes, and cover the slightly-open ventilators with coarse scrim or tiffany. Shade any forward blooms by placing sheets of paper over them at a distance of 18 inches inside the house. By applying shading to the outside, other varieties which require all the light and sunshine possible may be unduly shaded. Such varieties as Mrs. A. T. Miller, Master James, Rose Ellis, Rose Pockett, Mrs. L. Thorn, Evangeline, Kara Dow and Reginald Vallis develop their blooms quickly. Mrs. Gilbert Drabble, Mr. Thornton, Master David, Countess of Granard, Marie Loomes, Francis Jolliffe, Edith Smith and other late-flowering sorts develop their blooms more slowly. All varieties of the incurved section should be fully developed, else their depth is much diminished, but they must not be forced open. The single-flowered section take the shortest time of any.

AVON.

GARDENING FOR BEGINNERS.

HOW TO PLANT ROSES.

THE year 1912 will be remembered for the great wealth of Roses produced, and hundreds of lovers of these charming flowers will wish to grow plants in their own gardens. The inexperienced cultivator will look for instructions as to the best way to prepare the soil and plant the trees. The following hints will prove useful to those who wish to plant trees of the various sections in open beds and near walls and fences for the furnishing of the garden generally.

How to Prepare the Soil.—A fairly heavy loam is regarded as an ideal one in which to grow Roses, and it is, undoubtedly, a splendid rooting medium. Such soil, however, is not found in all gardens; but, notwithstanding this initial drawback, the enthusiast will not hesitate to plant Roses in a rather light soil or in a gravelly or poor one. Where rich loam obtains, the cultivator will not need to do more than deeply trench it, leaving the subsoil at the bottom, as manure can be applied in the form of surface mulches afterwards. Light, sandy or gravelly soils must also be deeply trenched, and in each case the subsoil should be broken up with a garden fork and left below.

When Roses should be Planted.—The season for planting extends from October to March, both months included. The latter part of October and the whole of November is an ideal time for planting to be done if the soil is in good condition and the weather is open and dry. Certainly it is better to plant before Christmas, if possible, than afterwards, though the work may, and should, be done after Christmas if it is inconvenient to do it before. When the Roses are received from the nursery, they must be unpacked at once and, if the roots are dry, placed in a cistern or tub of water. No time must be lost in getting the trees planted, as exposure of the roots to the drying wind is harmful. If frost prevails, the bundles should be placed in a very cool shed or cellar, and be left there until a thaw comes. In this case also soak

PLANTING BUSH, CLIMBING AND STANDARD ROSES.

the roots for a few hours before planting is done. With regard to the actual planting of the Roses, the illustrations will greatly assist the inexperienced to understand how the work must be done.

The Illustrations.—Many plants are purchased similar to the one shown at No. 1. Very strong-growing varieties often possess roots of this kind, especially those belonging to the Hybrid Perpetual section. No. 2 shows a tree suitable for a wall or trellis. If any roots are damaged as shown at No. 3, such roots must be cut back with a sharp knife before planting. No. 4 shows how to plant a Rose which is intended for the covering of a trellis, screen or pergola. The tree should be planted between the posts for two reasons, namely, to avoid removing soil and loosening the posts, and

to avoid loss of trees through fungus, which often grows around posts. Healthy trees soon grow and cover all posts with branches. No. 5 shows how to make the holes for the plants. They must be several inches wider every way than the spread of the roots, and not too deep. No. 6 shows a standard Rose planted and staked, and it may be noted that the stake supports the head as well as the stem. No. 7 shows the right way to plant a Rose near a wall, with the centre, No. 8, well open. The centre of a wall tree always closes up first. The roots must be planted about ten inches or one foot away from a wall, so as to avoid the wall "footings" as shown at No. 9. Avoid overcrowding the plants in beds. Mixed varieties of Hybrid Perpetuals should be planted 18 inches apart. When one variety occupies a bed and is a strong-growing one, 2 feet must be allowed. The circles and crosses denote the position of the plants in a round bed. No. 11 shows how to plant Roses to cover low or high trellises. No. 12 shows the iron rods for supporting wires to which the branches are trained. Plant firmly and slightly deeper than the bushes have been growing in the nursery. G. G.

A USEFUL GREENHOUSE PLANT.

CRASSULA FALCATA, a South African succulent, is more generally known under the name of *Rochea falcata*, and as such it may be often met with in old-fashioned gardens. Introduced over a century ago, its merits are, in the present-day race for novelties, frequently over-looked, yet when in flower it is a really pretty plant. It is a plant of sturdy growth, the stout, upright stem being furnished with thick, fleshy, sickle-shaped leaves of a rather glaucous tone of colour. The flowers are small, bright red in tint, and disposed in closely-packed, flattened heads, the golden anthers forming a notable feature of the inflorescence. It is quite distinct from the old *Crassula*, or *Kalanthes coccinea*, which, by the way, is now included in the genus *Rochea*.

PLANTING ROSES AGAINST WALLS AND IN BEDS.

THE FLOWER GARDEN.**SWEET PEA NOTES.**

Autumn Catalogues.—As was promised in an earlier issue of *THE GARDEN*, notes will be given in this and succeeding numbers of the varieties which the leading specialists in Sweet Peas are offering. It has already been hinted that stocks of all the finest novelties, and also of many of the leading modern sorts, will be decidedly on the short side, and the man who orders early will have a far better chance of getting precisely what he requires or desires than the one who procrastinates and cannot make up his mind until the season is on the wane. "Order early" is an excellent motto. The best firms are all somewhat shy of giving definite information, and the promises are all qualified in some manner or another.

A Birmingham List.—Mr. Robert Sydenham openly avows the fact that he is not a raiser of novelties in Sweet Peas or anything else in the gardening way, but he has a wonderful capacity for finding the "swans" raised by others, and will always purchase stocks provided they are sufficiently bulky to be worthy of his consideration. Among his best, though all are not necessarily offered this season for the first time, is *Lilian*, a soft waved pink, flushed with buff, which has the happy habit of carrying four flowers on a stem. Visitors to the Royal International and other important shows will have made a note of it, because it was splendidly staged. *Princess Mary* is a waved medium blue very much in the way of *Flora Norton Spencer*, but a marked advance on that charming variety. It generally gives fours. The colour of *Zarina* is popular with practically everyone, and the *Spencer* form that Mr. Sydenham will offer is certain to have a warm welcome. It has been suggested on more than one occasion that *Lord Nelson* should be relegated to the region of superseded varieties, but there have always been those who maintained that it was fully entitled to its present position because there was no other blue comparable to it. Now that Mr. Sydenham has a true *Spencer* form, the old one will have to go to the wall, and the new-comer will spring instantly into the highest favour among growers for home decoration as well as for exhibition. It is described as standing the sun better than any other Sweet Pea of its colour, and as yielding four flowers on practically every stem under good management. *Cerise Spencer* is a hackneyed sort of description; it conveys an accurate idea of its colour, but not of the fact that it is nearly sun-proof, which is, after all, one of the most important of all recommendations. The varieties that emanated from this source last season have proved to be thoroughly worthy of culture, and they should be borne in mind in compiling lists for next year. The names and colours are: *Edith Taylor*, salmon rose; *Barbara*, salmon orange; *Lady Evelyn Eyre*, pink, suffused salmon, large; *Emperor*, scarlet, exceptionally fine; and *Thomas Stevenson*, which reigns supreme in its particular shade. This is not, as will be acknowledged, a formidable set, but it is a good one.

An Ingatestone List.—For some years Mr. E. H. Christy, The Beacons, Ingatestone, ranked with the leading amateur enthusiasts in Sweet Pea culture, and he has now blossomed forth as a grower and seller of seeds. He is one of the staunchest advocates of reduction in the number of varieties, but his list demonstrates the fact

that he does not see his way clear to fewer than five dozen. The selection is beyond question an admirable one, comprising as it does all the finest varieties in cultivation. Mr. Christy has not offered any novelties of his own raising, but no doubt he will do so before many years have passed. Up to the present he chooses the best of those introduced by others and grows them on his own land in Essex, where, we are all agreed, some of the finest Sweet Pea seeds that one could desire to have or expect to see have long been produced. In this list the number of seeds in a packet is stated "subject to crop," and I for one shall be much surprised if Mr. Christy is able to come within speaking distance of the quality in the case of many varieties which he is offering.

HORACE J. WRIGHT.

A BEAUTIFUL BULBOUS PLANT.

(*HABRANTHUS PRATENSIS.*)

THIS beautiful bulbous plant was introduced from Chili in 1840, and is considered by many to be of doubtful hardiness, though here it stands without any protection whatever. The treatment we give it is as follows: The bulbs are planted in September in borders deeply dug, with a liberal quantity of leaf-mould incorporated in the same manner as for *Daffodil* culture. They could no doubt be planted with almost as good results well into October. They are planted in rows 1 foot apart, 9 inches from bulb to bulb and 4 inches deep. After planting, the borders are given a coating of leaf-soil 2 inches thick. The only attention the plants then receive is an occasional stirring of the surface and the keeping down of weeds.

The soil here is sandy loam, and the gardens are situated six miles from the coast of Norfolk. Our largest border of *Habranthus* this year is 12 feet wide and has a south-east aspect. At the back is a wall 5 feet high, planted with Pear trees. The border starts 4 feet from the base of the wall. The bulbs are allowed to remain two years, when they are lifted and divided as soon as the foliage has ripened, which is about the end of June or early July, the small bulbs being planted by themselves to grow on to flowering size. The plants were very strong this year, and threw up flower-stems 18 inches to 2 feet high, with from five to nine flowers on each, seven being quite common. Last spring, before flowering, the plants withstood frosts up to 22°.

The original bulbs in these gardens were given to my grandfather by the late Rev. Nelson of Aldborough forty years ago, and his advice was to plant them in a warm position 10 inches to 12 inches apart and leave them undisturbed. There are several other gardens in this district where *Habranthus pratensis* is flourishing, the bulbs being distributed from the same source. This autumn we are planting *Habranthus* in beds quite in the open, as last season we had some small bulbs planted to grow on in beds fully exposed, and they did as well as could be desired. It would seem that this beautiful subject is more hardy than is generally supposed. Perhaps these few notes may induce others to try this plant, which well repays any labour expended on it. I may add that last May we had over eight hundred spikes, which, with their vivid colouring, made a display not easily forgotten.

E. G. DAVISON.

Westwick Gardens, Norwich, Norfolk.

PREPARING NEW BEDS FOR ROSES.

IF one would have good Roses, he must grow them in his heart." The late Dean Hole was not far wrong when he made the above remark, and it is true that if one possesses a real love for the flower, he will see to it that good soil is prepared for the plants. I am afraid many amateurs are very often induced to go to unnecessary expense in purchasing special soil from a distance, when perhaps their own soil is good enough. If one possesses a light, sandy soil, then by all means add some loam and, if possible, pulverised clay, and also a liberal amount of good cow and pig manure. Roses are gross feeders and require plenty of nourishment, and nothing can be better for them than natural manure.

If the soil happens to be a heavy clay, this needs well breaking up and some burnt earth added. Perhaps the ideal soil is such as this. We do not know the value of burnt earth, especially to blend with clay soils, and a cartload or two of this is a good investment. In preparing new beds or borders for Roses, do not be induced to add all sorts of compounds, such as leaf-soil, and be very chary of adding the various remedies for the extermination of insect pests. My own opinion of these is that the remedy is often worse than the disease. If there are insect pests, lay the soil out thinly and allow the birds to pick it over; and they will do this most thoroughly.

All beds or borders should be trenched 2 feet deep, and if of a light nature, trench 3 feet and add plenty of good cow-manure to the lower soil. My plan is to open a trench 3 feet wide and any convenient length. Take out a spadeful in depth all along the trench and also its width. Wheel this away to the end of the trench. Now shovel out the loosened soil and also wheel it away. Fork up the next layer with a good deep fork; then spread over 3 inches or 4 inches of good manure and fork the ground over again. Add 6oz. of basic slag to every square yard. This is best put on at the same time as the manure. Now mark out the second trench and dig the top soil into trench No. 1. Shovel out the loose soil, and trench No. 1 is finished. If any soil is to be added, this can be done as the work of turning over is carried out. Should there be Roses in the borders that one does not wish disturbed, it is very easy to avoid these as the trenching proceeds; but it is far better to dig as much of the soil as possible, rather than adopt the very bad plan of just opening holes wherever a Rose is to be planted.

For ramblers and standard Roses that are to be isolated, also for weeping Roses, good large holes should be dug out fully 3 feet deep, and as much in width and length. One important detail, viz., drainage, must not be overlooked. Roses abhor a water-logged soil. If the drainage is not free, artificial means should be adopted to make it so, and a few inches of large stones, clinkers or brickbats, placed 3 feet deep, will generally effect our purpose, providing a fall is made for the superfluous water.

Perhaps the greatest enemy of the villa gardener is the unskilled jobbing man, who will not prepare the soil properly for the Roses he has to plant. I would strongly urge upon all amateurs to see that the soil is well broken up to a depth of 30 inches at least; then one may expect good results, providing sound well-rooted plants are set cut.

DANECROFT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Crown Imperials (*Fritillaria imperialis*) are fine subjects for the borders and give their stately drooping flowers early. A good rich soil is suited to their requirements, and before planting, which may be carried out now at any time, see that the position they are to occupy is liberally treated with decayed farmyard manure. There is a variegated variety which is also very effective.

Leucojum aestivum, or the Summer Snowflake, may be planted in the borders or elsewhere, and will give a display of its Snowdrop-like, but larger, flowers during summer. Being perfectly hardy, it is no trouble. Plant about three inches below the surface.

Calceolaria alba.—This is an interesting and pretty plant for the borders and front of the shrubberies, but, unfortunately, none too hardy. A few cuttings taken now and wintered in a cold frame will ensure the plant being perpetuated next year in the event of the old plants succumbing.

Senecio glastifolius.—This, too, is a grand subject for late summer and autumn blooming, and an exceptionally free grower, producing showy flowers of much value for vase and table decoration. In a mild winter the plants will pass through it unharmed, but either a little seed should be reserved or cuttings taken as advised for the above.

Cape Figwort (*Phygelius capensis*).—This plant has been very effective this season, flowering profusely. Cuttings will root readily, and, if not already taken, should be secured at once. In warm localities it forms quite a large bush, but is never absolutely safe from frosts. With us it only makes an annual growth, and with the protection of some cinder-ashes round the base we generally manage to keep it. It also makes a fine subject planted against a wall in a sheltered position.

The Rock Garden.

Protecting Plants from Rains.—There are several subjects which are liable to be lost if exposed throughout the winter months to continued rains, and therefore some device should be used so that a sheet of glass of sufficient size can be raised above the plant and held secure in a slightly slanting position. There are various methods. Some people prefer a wire support, or even four wooden sticks with wire to go over the glass will suffice; but the arrangement should be simple and one where the glass can be easily detached and the frame stored away when not needed.

Labelling.—This, when done, should always be as neat as possible, but in many gardens it does not receive the attention it deserves when one considers the educational value to be gained. Small metal labels, stamped with a set of small letters, are cheap and lasting, as well as neat, and should, wherever possible, be placed just in front of the plants. Now that many plants are losing their growth, care should be taken that they are not disturbed, and here again the value of a label becomes apparent.

Plants Under Glass

Nerine Fothergillii.—This is a fine bulbous plant for autumn flowering in the greenhouse, and the cultural requirements are not very exacting. Nernes should not be disturbed oftener than is necessary, and unless the stock is wanted to be increased, leave them alone. While making their growth give plenty of water and manual assistance, and when thoroughly hardened off expose during the summer months to full sun and keep dry. This treatment, generally speaking, applies to all such Cape bulbous plants.

Gloriosa superba.—This attractive stove climber will, in most cases, be completing its growth, and as soon as it exhibits signs of yellowness it should be taken down from the rafters and tied to one or two sticks, water being gradually withheld from the plant, finally turning it on its side in a warm house to rest during the winter months.

Paneratiums.—When these have flowered, the plants should again be returned to a warmer house, and if any attention as regards potting is required, this may be given. Water newly-potted plants very carefully. Use a mixture of good turfy loam,

peat and leaf-mould, with the addition of charcoal and sand, using clean, well-drained pots.

Fruits Under Glass.

The Early Vinery.—With Vines that are started into growth before the close of the old year, it is absolutely necessary that they, as with all others, should have a season of rest, and during their resting period they should be exposed to all the air and, as far as is possible, a dry atmosphere. Often-times these houses have to accommodate flowering plants, but avoid the introduction of any that are affected with mealy bug, if possible.

Tomatoes.—To successfully grow Tomatoes through the autumn and winter months requires extra care and attention, and unless one has the benefit of a pit or house with a little fire-heat, they are best left alone. As much light as possible is requisite for their well-being; therefore a house in a suitable site and thoroughly clean should be chosen for them. A circulation of air whenever possible, with just enough fire-heat to maintain a buoyant atmosphere, careful watering, together with keeping the floor and surroundings dry, will help towards having them in a healthy condition. Keep the growth trained near to the glass and give a little top-dressing occasionally. Just a sprinkling of fine soil, with some fertiliser mixed with it, will stimulate root action.

The Kitchen Garden.

Chicory.—This is easily forced, and is so valuable for salads that a little may be started into growth as soon as one cares for it. The old growth should be twisted off and five or six roots placed in a large pot, placing soil or old Mushroom-bed material among them. Give a thorough soaking of water, and keep dark either in the Mushroom-house or by means of an inverted pot.

Rhubarb.—As the foliage dies down on the beds it should be cleared away, also any weeds or other refuse, the ground afterwards lightly forked up, and a dressing of decayed manure applied. Where early-forced Rhubarb is in demand, a few roots should be lifted and allowed to lie on the ground for a few days, and then taken into the Mushroom-house and kept moist, or they may be placed under the stage in a warm house and covered in.

E. BECKETT, V.M.H.

Aldenham House Gardens, Eistree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Gladiolus.—Corms of the many sections may be lifted at any time after this, preserving some soil about the roots and all the little bulbs which are useful to increase stock. Lay them meanwhile in a perfectly cool structure where they are safe from frost. The present year's seedlings and young plants generally should have a 3-inch or 4-inch layer of soil spread evenly over the beds as a protection from hard frost.

Tuberous Begonias.—By covering at night these are sometimes preserved till the last. This year, however, the early frost in September seriously crippled the plants, and, as a rule, they will now be quite ready to lift. I leave some soil attached to the tubers, dry them in a covered outhouse or vinery, and then store them in boxes till spring. If carefully lifted and the carpeting material is still looking well, the beds, after tidying up, will be presentable for a few weeks longer.

Propagating Hardy Flowers.—The latest batch of cuttings of Pansies and Snapdragons should be put in forthwith. Some growers take cuttings of Carnations of the Raby Castle and Countess of Fife types and plant them in cold frames, where they form roots before spring is much advanced. Where possible, it is preferable to root them in sand in a propagating-pit, boxing them off when ready and growing coolly, far superior plants being the result.

Phloxes.—These, with few exceptions, will now have finished flowering, and where they are massed by themselves they may now be lifted, divided and replanted. Young plants are, of course, much to be preferred, but by selecting the outer portions of the clumps, perfectly satisfactory results are obtained. I would like to replant Phloxes annually, but have to be content with only some special varieties. The Phlox is a surface

rooter, and even if the ground is trenched, the greater part of the manure they must be allowed should not be buried deeply. To get a mass of blooms, the plants should be not more than a foot apart.

The Bog Garden.

Saxifraga Andrewsii.—This pretty species flowers at this time, and is almost the only plant in bloom. It should be raised above the water-line to be moist but not wet.

Meconopsis.—The foliage of *M. integrifolia* is very handsome if the plant is grown in the same way, and those who have a stock in pots might try some planted thus, that is where the natural soil is too light and porous to suit them.

General Work.—Quite a number of plants will now be past, and the stems should be cleared off—Liliums, for instance—and the decaying foliage of Arrow-heads, Water Plantains, &c., taken away. Forget-me-nots which have overrun their positions should be cut back, and, to finish all, a thin layer of rotted manure and soil be evenly distributed all over the soil where exposed.

The Plant-Houses.

Perpetual-flowering Carnations.—As many cuttings as can be secured should now be taken and rooted in sand in the propagating-pit. January cuttings may be preferred in the South, but autumn-struck cuttings certainly produce the better plants in the North. The cuttings themselves are of better quality, and the young plants are sufficiently forward by the end of January to go on with the advancing light and heat. Plants full of flower and buds in beds outside may be lifted and potted for present decorative purposes.

Heaths.—These are usually purchased at this season, and are sometimes allowed to get so dry at the root as to last only a short time. Much depends on the kind of structure in which they are placed, but the soil should be always kept moist, else the fine roots die and the plant follows. Much the same treatment is desirable for *Epacris*, but the plants are less susceptible to harm from occasional soil dryness.

Euphorbia fulgens.—This gloriously-coloured old flower should now be well forward, and growth should not be so much striven for as consolidation, so that as long sprays as possible may be flowered. The plants need only a temperature of 50° to 60°, and must not be overwatered in the meantime. Once the flower-buds are formed, occasional slight applications of sulphate of ammonia will deepen the scarlet.

Maidenhair Ferns.—These need to be merely kept in a frost-proof house through the winter, the fronds, if no damp is permitted, standing much better than if kept in a warm structure, and the new growths are much stronger in spring. Small plants will need to be watered with care, else, if too dry at the root, the fronds will wither. Large plants, on the other hand, will stand for weeks without water at the root.

The Vegetable Garden.

Tomatoes for spring fruiting should be repotted to stand over the winter, using a rather light compost. The plants should not be placed in too much heat, else they will not fruit, and must be kept rather dry at the root.

Celery.—Rust has been rather bad in this locality, and the crop consequently shortened. Repeated dustings with flowers of sulphur hindered its extension here. Before late rains soil should be placed well up the stems of the latest batch, finishing off the trenches two or three weeks hence when the soil has become somewhat settled.

Peas.—The full pods should be regularly picked off and kept for use in a cool place. The reason for this is lest frost should destroy the crop, which, if treated as above, will usually afford pods for a fortnight or so after the plants are killed.

Artichokes.—Cut over the stems of Jerusalem Artichokes 6 inches or 9 inches from the ground. The roots in the meantime will be the easier to raise, and the stems after this are no use to the crop. Strongly-grown Globe Artichokes are still producing small heads, and, like Pea pods, must not be allowed to remain on the plants to be frosted. It is worth while to detach suckers from the old plants and lay them in among coal-cinders or sand to be planted out in spring.

R. P. BROTHERSTON.

Tynningame, Prestonkirk, N.B.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

TO SOW FERN SPORES ON A WALL (Avonbrook).—As your wall is new, it is probable that you would do better to defer the sowing until spring. We presume that there are moderately wide crevices between the stones or bricks. That being so, it would be a good plan to take away a little of the mortar and insert a small piece of fibrous peat and a few chips of soft stone or brick. On the surface sow the spores during moist weather, but take care that the places where the spores are sown are so arranged that a heavy storm will not wash them off. If you have plenty of spores, a few might be sown now, and the remainder stored in envelopes or bottles in a cool place until spring. Another way in which you might deal with the wall is to sow the spores in pots or pans made up of sterilised soil, placing them in a cold frame. When the green, moss-like growth of the first stage in the Fern's life-history is fairly well advanced, remove it in small patches and introduce it to crevices in the wall during moist weather. Should drying winds be experienced after the completion of the work, it would be a good plan to moisten the wall several times a day.

ROSE GARDEN.

GRASS AN TEPLITZ BADLY MILDEWED (X).—We think you would do well to cut away the badly-mildewed parts. All affected growths and foliage should be burnt at once to prevent the spread of disease. We should advise a good spraying after the cutting has been done, using either Cyllin Soft Soap or V2 K Fluid. Either of these applied with a fine sprayer, and repeated at intervals of three or four days, will keep mildew in abeyance.

MANURES FOR ROSES (A. N.).—As you are unable to obtain sufficient stable or cow manure for your Rose beds, we do not think you can do better than use Wakeley's Hop Manure. This is composed of spent Hops treated with chemicals, and, in addition to supplying plant food, adds humus to the soil. For this reason it is a good substitute for natural manure. It can be dug into the soil when new beds are being prepared, and can also be lightly worked in between established bushes.

SWEET BRIAR HEDGE (K. D.).—A Sweet Briar hedge would be a very nice addition to the old-fashioned garden, and this plant will grow almost anywhere, certainly in the North of Ireland. The plants are procurable from any of the well-known Rose nurserymen who advertise in our columns, and usually they cost about 20s. to 25s. per hundred; or you can obtain extra strong plants at an advanced price. Plant the Sweet Briars in November, and see that the soil is dug 2 feet deep and 1 yard in width for a single row of plants, setting them about eighteen inches apart. The walks should be about three feet wide.

FRUIT GARDEN.

PEAR MIDGE (G. P.).—The trouble is not due to the frost, but the fruits are attacked by the Pear midge (*Diphysa pyri*), to which we have referred several times recently. It is too late to collect the fruits now; it should have been done some time ago.

BLACK CURRANTS (R. B.).—The Black Currants were not in any way attacked by insects or fungi. The probable explanation of the trouble with them is that they had become dry, and that, with the water supply suddenly given, the interior swelled more quickly than the skin could keep up with. They were abnormally full of seeds, and this may account for some of the cracking, for the pulpy part of the Black Currant consists largely of the much-swollen testas of the seeds.

PEAR LEAF-BLISTER (H. M. B.).—The leaves of the Pear are attacked by the Pear leaf-blistery mite. The pest appears to have been spreading rapidly during the last few years, and it is the cause of considerable damage when numerous. The mites hibernate in colonies of several individuals under the scales of the buds, and, as soon as the leaves begin to develop in the spring, the mites enter them through the several openings, and their presence causes the production of a small reddish gall. If many mites attack a leaf, it frequently happens that the leaf falls

long before it ought to do so. The female lays a few eggs inside the gall and, after hatching, the young mites make their way to other leaves, which they enter, or may even enter fresh places on the same leaf, galls developing as before. There are several broods in a year, and the mite spreads with each one of them. About September the young mites make their way to the winter buds, there to pass the cold season. All young nursery stock, if there is any fear of it being infested with the mite, should be fumigated with hydrocyanic acid gas, and older stock should be sprayed while it is dormant with the Oregon Winter Wash, made by mixing 3lb. of quicklime and 1lb. of caustic soda together, and slake with hot water in which 3lb. of flowers of sulphur have been well stirred. Stir the mixture and add 3lb. of common salt. Allow to boil for some time, then add water to make up to ten gallons. At about the end of May or in June, perhaps some good might be done by spraying with paraffin emulsion or with a nicotine wash.

MISCELLANEOUS.

INSECTS EATING LEAVES AND CROWNS OF WATER LILIES (G. W., Surrey).—The only thing we can suggest is that you have the pond thoroughly cleaned out next winter, removing all mud, soil and plants. Then make up beds of new soil and plant a fresh lot of Water Lilies. When once a pond and the plants become badly infested with such a pest, there is little use in trying to combat it by the use of insecticides, for what would kill the insects would be likely to kill the plants also.

LARVÆ FOR IDENTIFICATION (M. M. E.).—The grub sent is one of those known as surface caterpillars, and is apparently that of the Turnip moth (*Agrotis segetum*). There are several species with similar habits, burrowing into the ground during daylight and feeding on a variety of plants during the night. The best method of dealing with them, since no poison can with safety be used upon Lettuce, is to hand-pick them. Searching round the plants attacked to 2 inches down will not fail to reveal the pests if they are present. They are easily killed, and instantaneously, by dropping them into boiling water or paraffin.

INSECT PESTS (Miss K. D.).—Earwigs are sometimes very annoying, and occasionally troublesome. They are not without redeeming features, however, for they are carnivorous and devour some kinds of noxious insects. Where they are very numerous, they may be trapped by putting inverted pots with a little hay or straw near their haunts. They will seek refuge in the pots, and the latter may be examined daily and the earwigs shaken into hot water, or water in which a layer of paraffin is floating. Another good trap, used in a similar way, is furnished by dry Bean-stalks. They will creep into any dark crevice, and occasionally, but very rarely, get into the ears of people; but this is very rare indeed, and must be very uncomfortable for the earwig. Woodlice are best caught by putting hollowed-out pieces of Potato, hollow side downwards, near their haunts. These should be examined from day to day.

NAMES OF PLANTS.—Amateur.—1, *Phyllanthus* species; 2, *Tropeolum tuberosum*; 3, *Oenothera speciosa rosea*; 4, *Erigeron multiradiatus*; 5, *Geum chilense minutum*; 6, *Calyceanthus occidentalis*; 7, *Erigeron philadelphicus*; 8, *Sisyrinchium angustifolium*; 9, *Cistus*, probably *C. corbariensis*; 10, *Veronica Hectori*; 11, *Rose*, variety not known; 12, *Spiraea discolor*; 13, *Menziesii triuphans*; 14, *Spiraea* species, flowers required for identification; 15, *Cistus villosus*; 16, *Aralia chinensis canescens*; 17, *Acaanthus mollis*; 18, *Cornus alba Spæthii*; 19, *Echeveria* species; 20, *R. A.*—1, *Iuula eusifolia*; 2, *Serratula* species; 3, not recognised; 4, *Aster Linosyris*.—*Thornton-le-dale.*—*Lonicera sempervirens* (the North American Honeysuckle).—*N. N.*—1, *Juglans nigra* (Black Walnut); 2, *Juglans regia* (common Walnut).—*F. Dean, New Southgate.*—Yellow flower, *Statice Boudoulli*; blue flower, *Statice sinuata.*—*Jasom.*—*Sparmannia africana* (the African Hemp).—*D. M. M.*—*Chrysanthemum segetum* (Corn Marigold).—*Mrs. A. T. Ferris.*—We believe the Rose to be the Hybrid *Polyantha floribunda.*—*F. Lurani.*—*Rosa indica sanguinea.*

NAMES OF FRUIT.—C. A. R., Kent.—1 and 9, *Doyenné du Comice*, dessert; 2, *Beurré Hardy*, dessert; 3, *Beurré d'Anjou*, dessert; 4 and 6, *Brown Beurré*, dessert; 5, *Cox's Orange Pippin*, dessert; 7, *Baronne de Melo*, dessert. There was no No. 8. We cannot undertake to return samples.—*W. M., Chiswick.*—Yes; *Beauty of Kent.*—*Mrs. C., Hants.*—The same Apple is known in this country as *Emily Childs.*—*Mrs. V. G. K., Dorset.*—Apple *Gravenstein*, the true variety.—*Mrs. G., Oxford.*—1, *Catillac*; 2, *Marie Louise*; 3, *Urbaniste.*—*Perplexed.*—*Beurré Hardy.*—*A. R. L., Hants.*—1, *Striped Beaufin*; 2, *Durondeau*; 3, *General Todleben.*—*R. G.*—1, *Marie Louise*; 2, *Beurré Hardy*; 3, *Gansel's Bergamot*; 4, *Beurré Clairgeau*; 5, *Swan's Egg*; 6, too poor to name; 7, *Durondeau*; 8, *Bismarck*; 9, *Lady Henniker*; 10, *Hawthornden*; 11, *Yorkshire Beauty*; 12, *Wellington.*—*F. Clarke.*—The Apple you send is *Maltster*. It can be used for dessert or cooking. We hope you will subscribe to THE GARDEN regularly now.—*E. H.*—1, *Beurré Diel*; 2, arrived rotten; 3 and 6, *Marie Louise*; 4, *Beurré Superfin*; 5, *Pitnaston Duchess*; 7, *Doyenné du Comice*; 8, *Beurré d'Anjou*; 9, *Vicar of Winkfield*; 10 and 19, *Beurré Hardy*; 11, *Louise Bonne de Jersey*; 12, *Aspasie Aucourt*; 13, *Comte de Lamy*; 14, *General Todleben*; 15, *Bergamotte Espéren*; 16, *Duchesse de Angoulême*; 17, *Beurré Bachelier*; 18, *Doyenné Boussoch.*—*J. E. G. L., Chestow.*—*Pear Urbaniste.*—*Mrs W., Ipswich.*—1, *Jean van Geert*; 2, *Marie Louise*; 3, *Easter Beurré*; 4, *Apple Lady Henniker*. Nos. 2 and 3 are dessert, and No. 4 is used both for dessert and cooking.

SOCIETIES.

THE NATIONAL VEGETABLE SOCIETY.

The third annual exhibition in connection with the above society was held in the Clarendon Hall, Watford, on the 2nd inst. The Earl of Clarendon kindly opened the show, and in an excellent speech referred to the high quality of the exhibits and the good work which the society, in his opinion, were doing in bringing before the public vegetables of such high quality. Taken as a whole, the show was exceedingly good, and it is doubtful whether such a display has ever been seen anywhere in the United Kingdom so late in the year.

NON-COMPETITIVE EXHIBITS.

The Hon. Vicary Gibbs, Aldenhain House, Epsom (gardener, Mr. E. Beckett), showed a very beautiful and comprehensive collection of high-class vegetables. In addition to such kinds as Potatoes, Carrots, Leeks, Brussels-Sprouts, Onions and other ordinary vegetables, many of the rarer kinds were included, such, for instance, as *Salifly*, *Scorzoner*, *Celeriac*, *Capsicums*, *Aubergines* and *Kohl Rabi*. Needless to say, the whole of the vegetables were in the very pink of condition, and the staging was some of the best we have ever seen. We are indebted to Messrs. Sutton and Sons for the photograph of this exhibit, reproduced on page 524, all the vegetables included in it being grown from their seeds. Large gold medal.

Messrs. Doble and Co. had a beautiful collection of Potatoes, these being neatly staged in baskets on tiered staging. No fewer than fifty varieties were in the exhibit, these including *Improved Factor*, said to be a tremendous cropper; *Midlothian Early*, grown in Essex and Scotland respectively to show the difference of the skin texture in different soils; *White City* and the richly-coloured *Herd Laddie*. Silver-gilt medal.

The collection staged by Messrs. Barr and Sons, King Street, Covent Garden, was an exceedingly good one, and comprised a vast number of kinds, the whole being most artistically staged. Celery, Leeks, Cauliflowers, Beetroots, Onions, Lettuces, Carrots, Capsicums, Beans, Kohl Rabi and Potatoes were a few that called for special mention. Gold medal.

Messrs. Dickson and Robinson, Manchester, put up an attractive exhibit of their Premier Onion, a variety that has created considerable interest in various parts of the country. Silver medal.

Messrs. Gleeson and Co. of High Street, Watford, decorated the platform in a most artistic manner, tall Palms and other foliage plants being tastefully arranged on the main portion with beautiful examples of the florists' art, as well as a fine display of *Michaelmas Daisies* in the foreground. Gold medal.

Messrs. H. Lane and Sons, Berkhamstead, staged a large and representative collection of Apples, with some Pears and a few good dishes of Nuts. The large variety of Apples attracted much attention from visitors, who were able to see the best sorts for cultivation. Silver-gilt medal.

THE SOCIETY'S CLASSES.

In the premier class for twelve kinds of vegetables, the first prize was won by His Grace the Duke of Portland K.G. (gardener, Mr. J. Gibson), with a wonderful collection, in which the Carrots and Parsnips were exceptionally fine. Indeed, we doubt whether better have ever been seen. Second honours went to Mr. J. Hudson, Gimson Road, Leicester, his Onions and Cucumbers being of very high quality and the whole well staged. Third and fourth prizes were awarded respectively to W. H. Henderson, Esq., Serge Hill, King's Langley (gardener, Mr. F. L. Pike), and Messrs. Lobjoit and Son, Heston Farm, Hounslow.

In a similar class for nine kinds, distinct, first prize went to H. T. Tatham, Esq., Kendall Hall, Elstree (gardener, Mr. W. Gaiger). This exhibit was put up in a most attractive manner, the Carrots, Onions and Leek-calling for special praise. John Kerr, Esq., Rickmansworth (gardener, Mr. T. Avery), was a very good second, his Onions and Carrots being of particularly fine quality. C. H. Fritton, Esq., Grove Mill House, Watford (gardener, Mr. E. Woolf), was third.

For nine Tomatoes, one variety, quality and flavour to be the first consideration, there were eight entries, first honours going to Mr. J. Hudson, Leicester, for a fine dish of *New Emperor*. Second prize was won by the Duke of Portland, and third by Mrs. Denison, Little Gaddesden (gardener, Mr. A. G. Gentle).

For six Leeks there were three entries, first honours going to Mr. T. Jones, Raubon, for a fine half-dozen of *Champion*. Mr. J. Hudson of Leicester was a good second with the same variety, and Mr. T. Fellows, King's Langley, was placed third.

For a collection of six kinds of vegetables, distinct, to be grown by the competitor, open only to *bona-fide* cottage gardeners or allotment-holders in the county of Herts, there were nine entries, first prize going to Mr. W. Humphrey, Elstree, whose Cauliflowers, Onions and Celery were excellent. Mr. A. E. Dawes, Watford, was a good second. Third, fourth, fifth and sixth prizes were awarded respectively to Mr. H. Blake, Elstree; Mr. A. Madgwick, King's Langley; Mr. F. J. Gentle, King's Langley; and Mr. J. Day, Berkhamstead.

For nine Tomatoes the Rev. T. McMurdie was first with a superb dish, the whole being particularly well finished.

For six Red Intermediate Carrots there were no fewer than eleven entries, the first prize going to Mr. T. King, Bromham, Chippenham, for a wonderful half-dozen. Mrs. E. H. Denison was a close second, and Mr. J. White, Bampton, Oxford, third.

In a similar class for six Model Parsnips there were six entries, Mrs. E. H. Denison being a good first with

very high quality produce. Mr. J. White was second and the Rev. T. McMurdie third.

For six Long Crimson Beet, A. B. H. Goldsmidt, Esq., Mildenhall (gardener, Mr. T. Hatch), was first out of twelve competitors, second and third prizes going respectively to Mr. W. Humphreys, Elstree, and Mr. J. White, Bampton.

In Classes 1 to 10, prizes offered by Messrs. Barr and Sons, there was fairly good competition in most of them. For six Potatoes Scottish Chief, the first prize went to Mr. A. Evans, Radnorshire. Mr. J. White, Bampton, Oxford, was first for six Cabbages Little Queen; and Mr. K. Stannard, Panshanger, Herts, was first for six Cabbage Savoys Barr's New Cone-headed.

For six Stump-rooted Scarlet Carrots there were twelve entries. Mr. A. Evans, Radnorshire, being first with beautiful roots.

For six Crimson Globe Onions, H. T. Tatbam, Esq., was first, his bulbs being superb.

In Classes 11 to 21, prizes offered by Messrs. William Cuthbush and Son, competition was very good, particularly for Parsnips and Carrots. For six Onions, Mrs. E. H. Denison, Little Gaddesden, was a good first, the bulbs being large, yet of good quality. For six heads of Celery, Mr. W. Humphreys, Elstree, was a good first, Mrs. E. H. Denison and Miss Somers, Bushey, being second and third respectively.

Four entries were staged for six Leeks, the Rev. T. McMurdie, Weybridge (gardener, Mr. A. Basile), being

Birmingham, third. A similar number of dishes were staged in a class for Hercules Pea, Mr. T. Jones and the Rev. T. McMurdie being first and second respectively, third honours going to the Marquis of Northampton. For six Exhibition Leeks there were eight entries, the Rev. T. McMurdie being first with some splendidly-grown samples.

For a dish of Scarlet Runner Beans, Mrs. M. Knox was a good first, the Rev. T. McMurdie occupying a similar position for Giant French Beans. This gentleman was also first for Selected Alderman Peas with some particularly good produce. For three Marrows, Mrs. Denison was first, and Viscount Goschen received premier honours for a dish of Cartington Potatoes, there being ten entries, Miss Langworthy, Hollyport (gardener, Mr. T. J. Brown), was second, and Mr. E. Deakin, Hay Mills, Birmingham, third.

For six Perfection Intermediate Carrots no fewer than eleven exhibits were staged, Mrs. E. H. Denison being first with some remarkably good roots. Mr. W. Colman of Birmingham was a good second, and Mr. A. Evans, Radnorshire, third.

For six heads of Prize Pink Celery seven groups were staged, Miss Allead, Horsham (gardener, Mr. T. Sparkes), being placed first for some superb heads. The Rev. T. McMurdie was second, and Mrs. E. H. Denison third.

For six Market Favourite Beet there were thirteen entries, Mr. J. White, Bampton, Oxford, being first with particularly clean roots. The Marquis of Northampton was a good second, and the Right Hon. T. F. Halsey third,

Messrs. Clay and Son, Stratford, offered the prizes in Class 41 for six dishes of Potatoes, distinct. Mrs. Denison, Little Gaddesden (gardener, Mr. Gentle), took first place with the following varieties: Emperor, Royalty, King Edward VII., Excelsior, Snowball and Long-keeper. Mr. M. Hoad, Wellborough, Kent, was second; and the third place was taken by Viscount Goschen, Hawkhurst (gardener, Mr. J. Gilmour).

In Class 42 prizes were given by Messrs. Watkins and Simpson for the best collection of vegetables grown from their seeds. Messrs. Lohjoit and Son, Hounslow, were awarded the first prize for a very good exhibit.

In Classes 43 to 54 the prizes were offered by Robert Sydenham, Limited, Birmingham. In Class 43 some excellent collections of vegetables were staged, and the judges awarded the first prize to Mr. T. Jones, Ruabon, for an excellent exhibit which consisted of Autumn Giant Cauliflower, Ailsa Craig Onion, Up-to-date Potato, Dwarf Gem Brussels Sprouts, Hollow Crown Parsnip, St. Valery Carrot and Holmes' Supreme Tomato. The second award was given to Mr. J. White, Oxford.

Class 44, for eight distinct vegetables, was not so keenly contested as the previous class, but all entries were of excellent quality and were well staged. The first place was taken by Mr. E. Deakin, Birmingham, and the second by Messrs. Lohjoit and Son, Hounslow.

In Class 45 prizes were offered for the best eight Onions of one variety, and the premier award went to Mrs. Jenner, Wicmore Castle (gardener, Mr. W. Wheeler), for some excellent bulbs of Ailsa Craig.

In Class 46, for six Lyon Leeks, the first prize was awarded to the Rev. T. McMurdie, Woburn Park, Weybridge; and the second to Mr. E. Deakin, Birmingham.

The first award in Class 47, for eight Tomatoes, was given to Mr. E. Deakin, Birmingham, for a splendid dish of Holmes' Supreme. The second prize was won by Mr. J. White, Oxford, for a dish of Perfection.

Class 48, for three Cauliflowers, contained some excellent specimens, and the Rev. T. McMurdie of Weybridge (gardener, Mr. A. Basile) carried off the premier award for three splendid heads of Autumn Giant.

Class 49, for two dishes of Potatoes, was fairly well contested, and the first and second awards were given to R. H. Ling, Esq., Berkhamsted (gardener, Mr. D. Bedford), and the Rev. T. McMurdie, Weybridge (gardener, Mr. A. Basile), respectively.

In Class 50 competition was very keen, and the six heads of Celery for which the Rev. T. McMurdie was awarded the first prize deserve special mention. The variety shown was Bibby's Defiance. The second prize was won by Mr. T. Jones, Ruabon, with the same variety.

In Class 51 prizes were offered for eight Turnips. The first prize was won by R. H. Ling, Esq., Berkhamsted (gardener, Mr. D. Bedford).

Class 52 (six Parsnips) contained some splendid roots, and Mr. J. West, Oxford, carried off first honours for six almost perfect specimens.

In Class 53 (six Carrots) all the exhibits were of fine quality, and Mr. J. White, Oxford, took first place for some splendid roots of St. Valery; and Mr. T. King, Chippenham, was awarded the second prize for specimens of the same variety.

The quality of the exhibits in Class 54, for six Long Beet, was not so marked as in the two previous classes, but the first-prize exhibit awarded to Mr. E. Deakin consisted of excellent roots.

Messrs. J. K. King and Sons, Coggeshall, offered prizes in Class 56 for a collection of vegetables grown from their seed, and the second prize was given to Mr. G. Rickett, Croyley Green, the only exhibitor in this class, no first prize being awarded.

In Class 55 the prizes were offered by Messrs. Gleeson and Co., Watford, for a collection of vegetables grown from their seed. The first prize was awarded for an excellent exhibit to the Marquis of Northampton, Castle Ashby (gardener, Mr. A. R. Searle), and the second to H. T. Tatbam, Esq., Elstree (gardener, Mr. W. Gaiger).

The entries in Class 57 for three dishes were very numerous and the competition keen. The first prize was awarded to Mrs. E. H. Denison, Little Gaddesden, Herts (gardener, Mr. A. Gentle). The winning dishes consisted of Potatoes King Edward VII., Royalty and Snowball. Viscount Goschen, Hawkhurst (gardener, Mr. J. Gilmour), obtained the second prize. Prizes in this class were given by Messrs. H. Lane and Son, Great Berkhamsted.

The society's classes open to amateurs and cottagers only were 58 to 75.

Class 58 (six kinds of vegetables) was well contested, and Mr. H. Keep, Aldermaston, was awarded first prize for some splendid vegetables. Mr. W. Coleman, Buckingham, obtained second place.

In Class 59 prizes were offered for three kinds of vegetables. The first prize was taken by Mr. H. Andrews, Berkhamsted, with Cauliflower, Celery and Ailsa Craig Onion. Mr. C. King, Chippenham, was awarded the second prize.

THE NON-COMPETITIVE EXHIBIT OF VEGETABLES SHOWN BY THE HON. VICARY GIBBS AT THE NATIONAL VEGETABLE SOCIETY'S EXHIBITION.

first with beautiful produce. Mr. R. Staward, Panshanger, was second, and Mrs. M. Knox, Holt Hatch, Alton, Haunts, third.

In Classes 22 to 25, prizes offered by Messrs. Dickson, Brown and Tait, the entries were not quite up to the average. C. H. Fritton, Esq., Watford, was first for a truss of Tomatoes; Mr. T. Jones, Ruabon, first for two Cucumbers; the Marquis of Northampton, Castle Ashby (gardener, Mr. A. R. Searle), first for Cauliflowers with beautiful curds, and also for six heads of Celery, these being particularly fine.

In Classes 26 to 39, prizes offered by Messrs. Dickson and Robinson, the competition was very keen, particularly for Leeks, Carrots, Celery and Cauliflowers. For two bunches of Moneymaker Tomato, H. W. Henderson, Esq., King's Langley (gardener, Mr. F. L. Pike), was a good first with well-finished produce.

For six Premier Onions, J. Kerr, Esq., Rickmansworth (gardener, Mr. T. Avery), was first out of nine competitors; second and third prizes going respectively to Miss Jenner, Wenvoe Castle, Cardiff (gardener, Mr. H. Wheeler), and the Right Hon. T. F. Halsey, Hemel Hempstead (gardener, Mr. H. Folkes). The whole of the produce in this class was of exceptionally good quality. For thirty pods of New Lancastrian Pea there were seven exhibits, Mr. T. Jones, Ruabon, being first with splendid pods. The Rev. T. McMurdie was second, and Mr. W. Colman,

competition being very keen. Mr. W. Coleman, Buckingham, was first for a dish of Runner Beans, these being exceptionally good. J. Kerr, Esq., was placed second, and the Rev. T. McMurdie third.

The exhibits of Cabbage Lettuce Lord Kitchener were exceptionally fine, the first prize collection, staged by H. W. Henderson, Esq., King's Langley, being the best we have ever seen at this season. Mr. F. J. Gentle, King's Langley, was a good second, and the Rev. T. McMurdie third. For Standard Cauliflowers, Mr. W. Coleman, won in the order named, the whole of the produce being excellent.

For six Manchester Market Turnips, Mrs. E. H. Denison was first out of fourteen exhibitors, the roots being exceptionally clean and even. Mr. J. White was a good second with larger roots, and J. Kerr, Esq., third. Mrs. Denison was also first for six Selected Sugar-loaf Cabbages, J. Kerr, Esq., occupying a similar position for six Parsnips.

Competition was very keen in Class 40, in which prizes were offered by Mr. W. E. Sands, Ireland, for two dishes of Potatoes, one each of Erio's Queen and Irish Hero. W. H. Henderson, Esq., King's Langley (gardener, Mr. Pike), took the first prize; Mrs. E. H. Denison, Little Gaddesden (gardener, Mr. A. Gentle), the second; and the third was awarded to the Hon. Miss Plunkett, Dundalk, Ireland (gardener, Mr. R. Bloomer).

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

A Beautiful Rock Garden Sedum.—One of the most beautiful plants in the rock garden just now is *Sedum spurium splendens*. Its dwarf, spreading habit is admirably adapted for draping a large boulder, while its brilliant, almost carmine flower-trusses are very freely produced. Plants such as this, which flower at a time when the rock garden is all too dull, are particularly useful.

The "Temple" Show.—We understand on good authority that the spring show of the Royal Horticultural Society, which has for many years been held in the gardens of the Inner Temple, will next year be held in the Royal Hospital Grounds, Chelsea, where the great International Exhibition was held this year. For some years past the Temple Show has been much overcrowded, and the site at Chelsea will afford better scope for exhibitors to display their skill and allow visitors to see the show in comfort.

Some Interesting Cape Heaths.—At the meeting of the Royal Horticultural Society held on the 8th inst., considerable interest was manifested in a collection of Cape Heaths shown by Lady Grey. These were all cut sprays which had been shown at an exhibition of wild flowers held at Caledon, Cape Colony, on September 14, and were brought direct from there by Lady Grey. Several of the species were unknown to growers present at the meeting. At one time Cape Heaths were cultivated very largely in this country, but now well-grown examples are seldom met with.

Good Late-flowering Roses.—Although from 6° to 8° of frost had been registered for several mornings, and heavy fogs had existed for nearly a fortnight, the following Roses were blooming freely on the 14th inst. in an Essex garden: *Grüss* an *Teplitz*, *Gloire de Dijon*, *Frau Karl Druschki*, *Zephyrine Drouhin*, *Duchess of Wellington*, *Jas. Coey*, *Mrs. A. Munt*, *Konigin Carola*, *Margaret*, *Mme. Jules Gravereaux*, *Lady Alice Stanley*, *Mrs. Alfred Tate*, *La France de '98*, *Betty*, *Gustave Regis*, *Longworth Rambler*, *Margaret Molyneux*, *General Macarthur*, *Amateur Teyssier* and *Jessie*. All had really good, well-coloured blooms. *Jessie* has never been out of flower since the first week in July, and every young growth is covered with buds.

Stone Edgings to Flower Borders.—When visiting the gardens at Aldenham House, Elstree, a few weeks ago, we were interested to find that the flower borders which skirt the paths in the kitchen garden were edged with rough sandstone. This has taken the place of the grass edging that used to be there. The irregularly-shaped pieces of sandstone have been let into the soil, so that they are about six inches above the level of the pathway and form an edging some eighteen inches in width. Among the stones a number of the stronger-growing

alpines are planted, and the effect is most pleasing. The taller herbaceous plants are set well back, so that they do not overhang the alpine plants. In those gardens where a rock garden proper cannot be accommodated, a suitable home for a great many alpine plants could be constructed on the lines suggested.

Crocus pulchellus.—One of the most beautiful, although not the most showy, of the true *Crocuses* of autumn is *C. pulchellus*, which came into flower some days before September had run its course. It has delightful small flowers of a kind of pearl blue, though varying considerably in the precise tint. It succeeds well in the border close to the front, but its real place is in the grass or in a rock garden. It looks well in either of these positions, although it is less liable to injury on the rockery than anywhere else. *C. pulchellus* is quite hardy, and is an inexpensive bulb to purchase.

The British Fruit Show.—It is gratifying to know that in a year such as the present, when climatic conditions have been far from favourable, fruit-growers in this country are able to produce such magnificent examples of Apples, Pears, Grapes and other fruits as those staged at Vincent Square on Thursday and Friday of last week. The Royal Horticultural Society is doing good work in bringing exhibits of home-grown fruits before the public, but we think even more might be done in encouraging the grading and marketing of Apples. A detailed report of the show will be found on another page.

Campanula Hillside Gem.—There would appear to be a good deal of the *C. Hendersonii* blood in this plant, and despite its distinct habit, taller growth and differently-coloured flowers, among other things, the plant might well be compared to an improved *C. Hendersonii*. It would appear more generally amenable to cultivation than the last-named, while its profuse flowering—July to October—should render it welcome to all. Even now in the early days of October it is giving quite a passable display, and is one of the very few of its genus now in bloom. Eighteen inches or 20 inches high, the plants need no support, and an established clump is very showy.

A Brilliant Autumn Flower (Zauschneria californica).—For autumn flowering this is one of the most brilliantly-coloured flowers in the hardy plant garden, one worthy of appearing here and there in varied aspects so that a continued flowering may result. Not a lover of over-rich soils, it is a moot question whether some of the more brilliant effects of which the plant is capable are not the result of wall planting, that type of it more particularly where the roots may descend deeply in rubble and soil and still find a congenial home for years. A like result may be secured in the larger rock garden, where crag and crevice having been studiously made, the plants have also been equally studiously planted.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

"A Visit to Some Irish Rose Gardens."—In THE GARDEN for October 12, page 513, column 1, line 23, for "Colleen" read "Coronation." The latter, a seedling of Messrs. Hugh Dickson, Limited, is the Rose referred to.—J. H. PEMBERTON.

Rose Alberic Barbier.—As an almost continuous bloomer among the wichuraiana Roses, Alberic Barbier seems to bear the palm, and this season it has been in flower for many months and is still flowering away in the beginning of October here in the South of Scotland. It is very fine on a pillar with its creamy white, yellow-shaded flowers.—SUB ROSA.

The Loquat Fruiting in the Open.—In the gardens of E. A. Owgrom, Esq., of Culver, about five miles from Exeter, a Loquat tree (*Eriobotrya japonica*) has, growing under a south wall, borne

Rose Irish Fireflame.—A note by "Danecroft" in your issue of October 5, page 499, attracts my attention, and with your permission I should like to correct the slight error that occurs therein in the name of this Rose; and it is perhaps all the more important that it should be done early, as there is already another Rose in commerce bearing the name of Flame. Messrs. Alex. Dickson and Sons' latest single is called *Irisa Fireflame*, and not *Irish Flame*. The error, I think, crept in at the Southampton Show, where this beautiful Rose made its first appearance. It was unanimously awarded the gold medal of the National Rose Society, and proved the sensation of the show. I have Mr. George Dickson's authority for stating that the correct name is *Irish Fireflame*—*Fireflame* by name and *fire flame* by nature. Beautiful as *Irish Elegance* is, and entitled as it has been to be called the most beautiful of all single Roses, the new-comer, in my estimation, will eclipse it. It is dazzling in its brilliancy, gorgeous in its colour-scheme—that is not a pretty word, but I can think

of bone-meal and half-inch bones being added at planting-time. Just before the buds showed colour a dressing of Bentley's Rose Manure was hoed in, using a Sproughton hoe, a very necessary implement in successful Rose-growing. Sunburst is undoubtedly one of the "great" Roses.—E. E. F.

—Your correspondent Mr. Cook, page 499, issue October 5, advises disbudding and retaining side buds, and so avoid poorly-coloured blooms; but my experience is that the flowers are borne singly on stout stems. I understand that for early forcing under glass this Rose is a failure, and I believe time will show that it is as fickle in colour as W. A. Richardson. Lately I have seen a great number of blooms come pure blush. I am looking forward to your able correspondent Mr. Molyneux in his "Notes on Newer Roses" to say what we may expect of this beautiful Rose.—WEST WORTHING.

Flower Shows and the Judges.—It has long been a matter of surprise to me that while in practically all competitions the names of the judges, umpires, referees, examiners, or whatever title they are known by are publicly announced, the reverse holds good in the majority of flower shows, for it is in their case quite the exception to learn the names of the judges. In the report of the large provincial shows, at which heavy prizes are given, one frequently reads of the points allotted to different exhibits by the judges, but never a word as to the identity of those chosen to adjudicate on the merits of the various subjects. It would, I am sure, be to many as interesting to know the names of the judges as it is to learn other particulars connected with the show. Our own Royal Horticultural Society and the Manchester and North of England Orchid Society publish the names of the members of the different committees who are present at each meeting, hence one may readily learn who has adjudicated upon any particular exhibit; but in the case of most shows the identity of the judges is not disclosed, at least to the general public.—H. P.

Judging New Roses.—Your correspondent Mr. W. Easlea makes an admirable suggestion in his article on "Judging New Roses," page 517, issue October 12, viz., that the National Rose Society should have a trial ground of its own, to which all members should have access. I feel sure it would answer in every way if it were tried, and that it would not be a financial strain on the society, as no doubt it would be the means of increasing the membership considerably. It would be a great boon to be able to judge for one's self the various habits of growth of new Roses. Most people have not the time to rush about all over the kingdom to various nurseries to inspect them, and it is impossible to form any idea of the quality of plants from the descriptions in the catalogues, as the raisers naturally "boon" their own productions. Furthermore, I would suggest that novelties should be sent to the new trial ground, and that the raisers should not be allowed to enter them for a gold medal for two or three years until their qualities have been thoroughly tested and approved by the judges of the National Rose Society. Most of us want good garden Roses for bedding. I do not suppose 90 per cent. of the members of the society care twopenny about the "exhibition" qualities of the flowers, so that anything that can be done to encourage the raising of good garden Roses would be cordially welcome, and the first step in this direction would be to allow members of the society to judge for themselves of the individual merits of each novelty.—L. B., Surrey.

AN INTERESTING DISH OF THE WATER LEMON (*PASSIFLORA LAURIFOLIA*), SHOWN LAST WEEK BY MR. JAMES VERT OF AUDLEY END GARDENS, SAFFRON WALDEN, AT THE EXHIBITION OF BRITISH-GROWN FRUIT.

several branches with fine ripe fruits on them. It is rather rare for the Loquat to ripen its fruits in the open in this country, but Culver is a much-favoured spot in a climatically-favoured county.—ROBERT VEITCH AND SON.

Albino Forms of *Geranium robertianum*.—I was interested in reading the second paragraph in the second column of THE GARDEN for October 12, for only six weeks ago, when at Droitwich, my old College friend, Frederick Baynes (who in 1870 had "tubbed" me for the first Lady Margaret Boat, St. John's, Cambridge, then second on the river, and Goldie at the stroke oar), sent his motor to bring me to his house at Summerhill, Kilderminster, and there in his old-fashioned garden I saw under the trees in the shrubbery the albino *Geranium robertianum* flowering freely in a comparatively wild state.—P. CLEMENTI-SMITH.

—An albino form of *Geranium robertianum* is to be found in the district between Southampton Water and Beaulieu. It is quite wild, and, I believe, established there.—C. AGNES ROOPER.

of no other that so fittingly describes this genus among Roses. Unfortunately, Messrs. Dickson do not hold a large enough stock to enable them to send it out this year, but they hope to put it on the market in 1913.—HERBERT E. MOLYNEUX, Southampton.

Rose Sunburst.—"G. T. W.," page 474, issue September 21, has been unfortunate in his experience of this variety. If he will pinch off the first buds as soon as they are formed, he will then have blooms of the intense apricot and orange shade so attractive. My plants have been superb, having freedom of growth and perfect blooms of the desired colour. If "G. T. W." will give it another trial, I am sure he will be pleased. I have known Sunburst for some time, and have not the slightest hesitation in saying it is the finest of its colour ever sent out by M. Pernet-Ducher, superb and useful for any purpose, and very fine under glass. The ground in which Sunburst has done so well was deeply trenched and enriched with good farmyard manure and basic slag, a mixture

A First-prize Basket of Flowers.—I am enclosing a photograph I have taken of a basket of flowers arranged by my daughter, Miss M. H. Ledgard, which won the first prize at Thorne Flower Show on August 14.—ARMITAGE LEDGARD, *The Manor House, Thorne, Yorks.*

Collarette Dahlia Queen Mary.—This is one of the finest of the new Collarette Dahlias, and a set of such beauty of colour and form as this would do much to popularise the Collarette varieties. It is one of the varieties which blooms freely and throws up its flowers well, instead of hiding them, as is too often the case with this type of Dahlia. The blooms are of a fine shade of bright rose, with a white disc and prettily tipped with white. The collar is a pleasing blush, the whole flower having a very beautiful effect. It has been honoured with awards, but its merit of a good habit is not so well known as it should be.—A. M. D.

Buddleia asiatica in Scotland.—This handsome Buddleia is highly appreciated in the gardens of Drumlanrig Castle, where it is cultivated on the walls of a temperate house. It is very handsome with its pleasing whitish foliage and its racemes of white flowers. It is but seldom seen, and it is an interesting question whether it may not prove hardy in the milder parts of the country. Should it do so, it would be an excellent companion to *B. variabilis* and *B. Colvillei*. It is said in some books to reach to only 3 feet high, but at Drumlanrig on a wall it is 10 feet or 12 feet in height against the back wall of a lean-to house. Mr. Inglis grows it well.—VISITOR.

Choisya ternata.—I notice with pleasure the increasing interest of garden-lovers in that beautiful shrub, *Choisya ternata*. I have grown it now for over ten years. For some reason or other best known to itself, it took over two years before it flowered properly, but now and for some years past it has never failed. I find it perfectly hardy in every situation. It has gone through 30° of frost practically without showing any signs of discomfort beyond getting the tips of its leaves pinched. I have it planted in clumps and isolated bushes and as hedges, and everywhere it responds to whatever attention it gets. It does not seem to be at all particular as to soil, but it flowers better on a south border. Cuttings on a north border began to flower at a very early age. I do not think I have had a single failure in rooting it. I root cuttings regularly every year, and I find that it is a most acceptable present to my gardening friends when I present them with a well-grown bush of my own striking. I do not know whether it had reached England in Keat's time, but I believe he must have meant the *Choisya* when he wrote "A thing of beauty is a joy for ever."—GUY CAMPBELL, *Thames Ditton.*

FORTHCOMING EVENTS.

October 21.—National Chrysanthemum Society's Executive and Floral Committee's Meeting.

October 22.—Royal Horticultural Society's Meeting and Exhibition. Lecture at 3 p.m. by the Rev. Professor G. Henslow, V.M.H., on "The Senses of Plants."

October 23.—Herefordshire Fruit, Root and Chrysanthemum Show (two days). Croydon Chrysanthemum Show (two days).

TREES AND SHRUBS.

THE CARE OF OLD TREES.

IF we are to judge from the neglected appearance of old trees in many gardens, the fact that a little timely attention would, in many cases, prolong their lives for an indefinite period does not appear to be generally recognised. Yet in some instances the preservation of such trees is absolutely necessary to maintain the privacy and charm of the garden, for their death may let in views of ugly buildings and other objectionable features. There are favourite trees, too, which people would regret to lose, whose lives might have many years added to them were they only taken in hand in time.

As a rule, injury to branch, trunk or root is the initial cause of decay. By these injuries spores

by some fungus disease, there is little chance of saving the tree. Sometimes, however, a decayed section of trunk may be noticed near the ground-line, which, if dealt with at once, may hold the disease in check. In such cases the bark should be cut away, together with any rotten wood, until living bark and wood is reached. Should the disease extend below ground, remove the soil and cut away any dead wood found about the base of the trunk or roots. The wounds must then be painted over with a strong carbolic acid solution, and, when dry, with coal-tar. Two coats of the latter may be necessary. Such wounds are often due to very slight injuries in the first place, such as a blow from a mowing-machine, a sharp knock with some heavy instrument, frost-bite or sun-stroke, which, if attended to at once, would go no further. In the case of injured bark, it is always a good thing to cut the injured part away and paint the wound at once with coal-tar. Another fertile source of injury is the piling of soil, short grass or other material about the trunks. Sooner or later such a habit leads to disaster, and the most satisfactory trees are always those whose upper roots are quite close to the surface of the ground, which may be seen by the junction of trunk and roots rising clear of the ground. Root injury also occurs after the ground has been badly waterlogged. On heavy, low-lying ground this condition may sometimes be noted after an unusually wet winter, or after a stream has overflowed its banks. Unfortunately, the injury is so far advanced before it can be detected that there is little hope of saving the trees. All that can be done is to open drains round about them, and if the ground is covered with grass, remove the turf and fork the ground over lightly to let in as much air as possible. A long spell of drought may also have a bad effect on trees, especially old ones growing in rather poor soil. Fortunately, such cases are fairly easy to deal with, for short growth and flabby leafage usually indicate weakness and a shortage of water, and the necessary steps can be taken in time to prevent the death of the trees. In such cases the turf must be removed from beneath the branches to the full radius of the branch system, the ground afterwards being lightly forked over and thoroughly watered, finishing the work with a surface-dressing, 6 inches deep, of well-rotted manure and leaves.

FIRST-PRIZE BASKET OF FLOWERS SHOWN BY MISS LEDGARD AT A YORKSHIRE SHOW.

of various kinds of fungus find an entrance. The spread of disease is often facilitated by the age and general weakening of the health of the trees, and decay goes on unchecked until the owners suddenly observe that a tree is either unsafe or a large portion of it is dying. Branches broken by storms are a fertile source of permanent injury if attention is not paid to them at once, while injury caused to the surface of exposed roots by cart wheels, wheelbarrows and other things frequently account for the commencement of root trouble. There are, however, many instances where trees have become seriously damaged, but still retain a fair amount of vigour, which may be rejuvenated if they are only given the necessary attention, and the following notes are directed to a few methods of procedure.

Root Trouble.—This is the most difficult fault to deal with, and if the roots are badly attacked

Trees treated in this manner show a remarkable access of vigour the following year. Impoverished soil may also result in the weakened health of large trees. In the case of surface-rooting trees a layer of good soil and well-rotted manure may be applied as a surface-dressing after lightly forking the ground, taking care to carry the new soil to the outermost parts of the branches, for it must be remembered that the best feeding roots are found thereabouts. Deep-rooting trees and surface rooters also may be improved by opening a trench about the outer parts of the branches and forking the soil back towards the trees until fibrous roots are met with, then filling the trench with good soil.

Damaged Branches.—This may arise from a variety of causes. Damage by wind is one of the most common, for after a large limb has been blown away, the head of a tree is seriously weakened, and, if nothing is done, more branches follow.

To check this two courses of action are open. One is to reduce the weight of the remaining branches by removing a good-sized part of each, and the other is to link the branches to each other for mutual support. The latter may be done by placing iron collars round each branch and fastening them together with chains. Better still, however, is the method of boring a hole through each branch, inserting an iron bar between each two, and screwing it up tight at each end with nuts, iron plates 4 inches square being placed between the nuts and the bark. Dead tops of branches often occur also. Trees in this state are said to be "stag-headed," and they are very unsightly among other trees. They may be improved by cutting the dead parts out well below the place where the dead wood ends, taking care to tar all the wounds so made. While performing the work care must be taken to retain the natural outline of the tree, even if it means cutting away a branch or two which are apparently healthy. After a good topping such trees as Oaks, Elms, Poplars and Chestnuts often become quite healthy again, and last in good condition for many years.

Injury to Tree Trunks. —

Diseased areas on the trunks of trees may often be traced to branch injury in the first place. Branches may be blown out and the wounded places left unattended, or pruning may be improperly done and snags left behind, which in time decay and communicate disease to the trunk and eventually to the heart of the tree. It is not an uncommon question to be asked, "What can be done for trees with large or small holes in the trunk?" Providing the branch system is generally healthy, it is possible to patch up such a trunk in a manner that will prolong the life of the tree for many years. The first thing to do is to cut away as much dead wood as possible, then paint the bare surface with a solution of carbolic acid, afterwards applying a coat of tar. When this has had time to dry, the hollow or hollows must be built up with cement and bricks. A facing of cement must then be given to make the surface level with the surrounding bark, and this when dry may either be coated with tar or be coloured like the bark. Some people cover such wounds with zinc or lead, but it is a bad practice, for dirt and damp get beneath the covering and in time create more decay. Dead branches must always be removed quite close to the trunk, and the wounds so made be tarred over. There is really no special time for doing this class of work, but when living branches have to be removed, the best time is between June and Christmas. As a rule, it will be found a good plan to go round all important trees at least once a year and attend to any necessary pruning or touching up. Once the pruning is properly done, a little attention keeps the trees in good order.

W. D.

A FREE-FLOWERING WALL SHRUB.

(ABELIA GRANDIFLORA.)

As a wall shrub for early autumn effect there are few subjects to equal *Abelia grandiflora*. This *Abelia* produces a veritable shower of rosy white flowers at a time when the glory of most other flowering shrubs has departed. *Abelias* are not very extensively grown in the open. Only three species, viz., *A. rupestris*, *A. uniflora* and *A. floribunda*, appear to be known in the gardens of this country. *A. grandiflora* is a seedling of Italian origin, and is regarded as a form of *A. rupestris*. The flowers are considerably larger

ABELIA GRANDIFLORA, A BEAUTIFUL LATE AUTUMN-FLOWERING SHRUB FOR A SOUTH WALL.

than those of the type, and the whole plant is of more robust habit. When grown outdoors it requires a warm position; a wall facing south seems to suit it best. Although not fastidious as to soil, *Abelias* may almost be classed as peat-loving plants; a mixture of loam and peat in about equal parts will make the most suitable compost. In mild districts, such as the southern parts of England and in Ireland, *Abelias* are known to do remarkably well in open situations; but in northern and inland counties their culture should only be attempted where a south wall is at command.

THE HEATH GARDEN.

THE LING AND ITS VARIETIES.

THE Ling, or *Calluna vulgaris*, is so closely allied to the Heaths that many people make no distinction between the two genera. A careful examination, however, reveals the fact that there is a very different leaf arrangement, in addition to other botanical differences. In *Erica* the leaves are usually arranged rather loosely in whorls, while those of *Calluna* are closely packed together and disposed in such a manner as to give the stems a four-angled appearance.

There is only one species of *Calluna*, but it is prolific in varieties, which differ so widely from each other and from the type that, given a selection of the best, a varied and interesting feature can be produced. As is the case with most other shrubs which belong to the Heath family, the various varieties of *Calluna* are impatient of lime; therefore they ought not to be planted in places where lime is present in the soil to any appreciable extent. They thrive excellently in peat, although it is not essential to their well-being, for very good results can be obtained by planting in sandy loam. Propagation may be effected by means of cuttings or layers. The former is the better way, for the young plants are usually more vigorous than those raised from layers. The cuttings should be made from small side shoots during August or September, and be inserted in pots of sandy peat placed in a close frame, or in a bed of sandy peat under a hand-light.

When the different varieties are used singly to form masses or groups, they are very effective, but they make a charming picture also when the various kinds are mixed. A mixture of the better kinds was noticed a few years ago in the nursery of Messrs. James Smith and Sons at Darley Dale, and I was informed that quite a number of customers had been so pleased with it that they had repeated it in their own gardens.

The variable nature of the plant may be noticed sometimes on a wide stretch of moorland where it forms the principal vegetation, for it is possible to find clumps which differ considerably from the type. Thus in some places the branches may be 2 feet high, while in others they scarcely attain a height of 6 inches. Then, again, it is found in some places growing in dwarf, compact tufts 2 inches or 3 inches high, and in other places it is so dwarf as to resemble a close-grown moss. On the same hillside the colour of the flowers may be found to vary from the familiar light red of the commonest kind to white or dark red. The forms with white flowers are the more popular, and it pays to grow them on purpose for cut sprays.

Of late years a considerable trade has arisen in supplying white Ling, or white Heather as it is more often called, to the markets of various towns in Scotland during August and September. Quite recently an ingenious ruse was noticed in the London suburbs among itinerant flower-sellers with regard to a substitute for white Heather. Seed-bearing plants of a wild *Lepidium* had been collected and sprinkled with whitewash. From a superficial glance these bore a resemblance to Heather, and people were induced to part with their pennies quite readily. The branches of the Ling are sometimes used for thatching, especially for summer-houses and fruit-rooms. They are also used occasionally for litter for horses, and the young shoots are greedily eaten by grouse.

Of the many kinds in cultivation, the following may be accepted as a good selection: Alba, alba rigida, alba Serlei and Hammondii, strong-growing, white-flowered varieties; alba minor and alba pumila, dwarf-growing, white-flowered varieties; Alportii and rubra, strong-growing, red-flowered; rosea, rose-coloured; flore pleno, double red; aurea and caprea, golden and copper leaved respectively; Foxii, hypnoides, minima and pygmæa, dwarf, forming cushion-like masses of greenery, but not free-flowering. D.

THE ROSE GARDEN.

NOTES ON NEWER ROSES.

(Continued from page 519)

HYBRID TEAS.

IF new Hybrid Perpetuals are few and far between, the same cannot be said of the Hybrid Teas. Their number is legion, and the term "Hybrid Tea" is like charity, inasmuch as it covers a multitude of "Roses," most of them undoubtedly Hybrid Teas, but others might with more correctness, I fancy, be placed in other classes. The Hybrid Tea is the fashionable class at the moment, and so a Rose with any pretensions (sometimes, I am afraid, without any) to that term goes into the Hybrid Teas and is allowed to remain there. If it was a matter of serious moment, it would have to receive attention; as it is merely a label, and very often only an expression of opinion, it is not worth while going too deeply into the question, and at that I will leave it; but it is curious how Time has its revenges, for the old rosarian despised the Hybrid Tea class and refused for some time to recognise it. What would he say if he came back, I wonder? The rosarians' year-books make very interesting reading, especially some of the early numbers, and they have much to say on the Hybrid Teas; but that is another story that will keep. Among the newer Roses, the Hybrid Tea is much in evidence, and, dealing with those varieties that may be considered exhibition Roses first, I come to

Alice Lemon (Hill and Co., 1911).—This is an American-raised variety. Such plants as I have seen of it have been very promising, and the flowers quite up to exhibition standard. It was (particularly early in the season) frequently exhibited. Messrs. F. Cant had a really good flower of it at the Southampton Show that was at one time in

the running for the best Hybrid Tea, but it had eventually to make way for an extraordinary flower of St. Helena, another new Hybrid Tea. It has, of course, not yet had time to get into general cultivation, but I am convinced it is worth a trial and is not likely to disappoint. Its colour is bluish white, shading to a deeper centre. The flowers are well formed, seldom come a bad shape, and are of the desirable high-pointed pattern.

Andre Gamon (Pernet-Ducher, 1910).—This is a bright carmine colour, of good shape, but it needs to be shaded, as there are not too many petals. It should be useful in a cool season, and as it is now to be had at normal prices, it might tempt those of our exhibiting friends who like its colour. It is quite a good garden Rose, and in general appearance is not unlike Mrs. A. E. Coxhead, but without the fine shape of that variety.

Avoca (A. Dickson and Sons, 1907).—This Rose has done well this year in contradistinction to its

Rose he has yet raised. There is certainly a charm about it that is very taking. I have seen it described as a scented Frau Karl Druschki, but there is nothing Druschki-like about it. It has a much more refined appearance, and has undoubtedly a lot of Tea blood in its pedigree. The centre of the flower bears a strong resemblance to Catherine Mermet at its best, and the outside petals to La France. The buds have a slight blush "flush" on them, but this is lost in the open flower, which is a pure white. It was awarded the silver-gilt medal last year, but gained the premier award of the coveted gold medal at the last autumn show of the National Rose Society. (Was that because some of the judges had in the meantime seen it growing at Portadown, I wonder?) It is everybody's Rose, always in flower, standing the sun and the rain and the frost as well as any Rose I know, and its flowers always come good. I know the half-a-dozen rows that were growing at Portadown were hunted up

AUTUMN IN THE HEATH GARDEN. LING AND HEATHER EFFECTIVELY GROUPED.

last year's record, which was poor. It was well shown by trade and amateur alike, a box at the "National" shown by Dr. Pallett being very good, and he also won the medal for the best Hybrid Tea at the same show with a flower of this variety. Its fault is a tendency to make too much wood, so it is only in an early season that we see flowers of it in time for the shows. It is a good crimson-scarlet, and flowers of that colour are always wanted. It received the gold medal of the National Rose Society at the autumn show in 1907. One would call it a rather late-blooming variety, and as such it should be grown by all Southern exhibitors.

British Queen (S. McGredy and Son, 1912).—Ah! Has it come at last, the perfect white Rose? Form, fragrance, free-flowering, fine foliage—all of these are undoubtedly present in this beautiful variety. I believe Mr. McGredy calls it the finest

and down to find a bad flower or a split bloom, and although each plant was searched, it was *non est*, and there must have been thousands of flowers out. There are not many Roses of which this could truthfully be written. Anyone who saw it growing, as those who were fortunate enough to be able to visit the Portadown nurseries after the Belfast Show this year did, could not fail to be impressed with this Rose. That was in mid-July, and I noticed that Mr. W. J. Grant, who visited the nurseries in late September, writing in a contemporary, has formed the same high opinion of its future. It is undoubtedly one of the Roses of the year, useful for all purposes. The half-a-dozen plants that have been growing in my garden have created a sensation among my visitors.

Southampton.

HERBERT E. MOLYNEUX.

THE FLOWER GARDEN.

SIMPLE ARRANGEMENTS FOR SPRING BEDS AND BORDERS.

NOW IS THE TIME TO PLANT.

THE preparation of beds and borders for bulbs has so often been dealt with that it is not necessary to refer to it in detail now. Having prepared the beds, allow a few days to elapse before planting. It is advisable to have a definite idea and colour-scheme, thereby ensuring a pleasing result in the spring. The following arrangement has produced charming effects in both borders and beds, and can be recommended as one of the best results from the smallest possible outlay, and, furthermore, can be used annually with very little additional expenditure. The outside edge of the bed (which may be of any design) will be yellow with the sun-loving Crocuses. These, once planted, should remain undisturbed, as they do not interfere with the planting or growth of summer plants. So long as Crocuses grow and flower well it is a mistake to move them. The corms (or bulbs) should not be put into a hole made by a pointed dibbler, but should be pressed into a fairly solid base of soil and covered to a depth of 2 inches to 3 inches. The corms should be in two or three rows at a distance of 1 inch apart. This allows them ample room to increase year by year.

Following the Crocuses we have a belt of blue in the single dark blue bedding Hyacinths. These should be planted in the same manner as Crocuses, to a depth of 5 inches, but need to be about eight inches apart. Although the Crocuses bloom first, their foliage forms a pleasing surrounding for the rather sparsely-endowed foliaged Hyacinth. We have now advanced 6 inches inwards, and the next three additions, together with that of the centre, will supply the necessary foliage to relieve the dreary barrenness of the bed. The first belt is one of white in the *Viola Purity*, which is quite cheap and within the reach of all. Five inches or 6 inches behind it is *Royal Sovereign*, a deep yellow rayless variety of vigorous growth and very free-flowering. Further in another 6 inches, a belt of *Maggie Mott* or *Mauve Queen* gives a pleasing colour.

The centre, probably quite a large space, can first of all be filled with scarlet single Tulips, which should be planted as advised for Hyacinths, but about four inches deep, and the surface filled up with the double *Arabis alpina alba*. This is by far the most free-flowering and vigorous of this section of spring-flowering plants, and is very easy to propagate. Take a cutting as you would a *Geranium* cutting and insert it in the ground about three inches apart. The Tulips grow well above, and the scarlet contrasts vividly with the white

Stock-like blossoms of the *Arabis*, which in their mass give a slight pleasant perfume.

From early April to the end of May and into June the bed is "a thing of beauty," the *Violas* and *Arabis* keeping it gay with blossoms till the time is ripe for the transplanting of the summer occupants. *Myosotis* and *Silenes* may be used, but the effect is not so pleasing, and the extra trouble they entail in raising from seed, &c., does not recommend them when the beautiful double *Arabis* will flourish direct from cuttings. A pleasing variation is an edging of *Scillas*, a band of *Snowdrops*, followed by a belt of *Iris reticulata*, the white, yellow and mauve *Violas*, and, instead of the *Tulips*, *Horsfieldii* *Daffodils* towering over a carpet of the double white *Arabis*. The *Daffodils*

recommend others to try these flowers in like situations. Any free-flowering and strong-growing sort is amenable to this mode of culture. The variety *Robert Parker* is used with telling effect at Kew, and the dwarfier-growing Italian *Starwort* (*Aster Amellus bessarabicus*) is likewise seen to great advantage. These flowers have leapt into popular favour within the last few years. They are specially adapted to informal grouping, and impart touches of colour warmly appreciated at this season.

SOME CHOICE BULBS FOR PRESENT PLANTING.

THE charming personality of many bulbous plants is nowhere seen to greater advantage than under conditions nearly approximating to their natural habitat.

The bare ground that invariably results from the dense leafage of a Beech wood on the chalk may be transformed into a carpet of green and gold in January and February with the little *Winter Aconite*, so freely does this subject naturalise on this shallow soil that tens of thousands of seedlings can be counted each spring around the parent plants, and the majority of these eventually reach maturity.

Similar results may readily be attained with numbers of other bulbous plants. *Anemone apennina* is an instance. This lovely subject, with its starry blue flowers, is a sun-lover from Southern Europe, and revels in an open, sunny spot in garden or woodland where the soil is of moderate depth and other vegetation not too rank to choke it out. I have used it on the outskirts of Beech coverts and mixed woods of Spruce, Firs and hardwoods, and it is a revelation how rapidly the warty tubers increase. *Anemone blanda* is less vigorous, and is unable to compete with coarse woodland growth. It is a plant for the choice border or rock garden, succeeding in either an east or west aspect, and flowering during February and March, quite a month in advance of *A. apennina*. Selected forms of *A. nemerosa*, such as *Blue Bonnet* and *robinsoniana*, are also best grown under like conditions. The fleshy underground stems of these are exceedingly brittle, and must never be unduly exposed to the air like other bulbs.

AN AUTUMN WOODLAND SCENE: MICHAELMAS DAISIES GROUPED FOR EFFECT.

require planting at least 6 inches deep, and cannot be planted too early in September. S. W.

PERENNIAL ASTERS AS WOODLAND FLOWERS.

It seems almost incredible that the value of perennial Asters or Michaelmas Daisies for colour effect in the woodland should so long remain overlooked. There are few flowers that succeed under the shade of trees even in the height of summer, and there are certainly no plants at this season of the year to rival the Michaelmas Daisy for this purpose. At Kew these beautiful flowers are grown in large informal clumps and massed here and there in well-chosen spots throughout the woodland. The effect is most pleasing, and we unhesitatingly

Double and single *Snowdrops* (*Galanthus*) succeed under a great variety of conditions, and are always excellent in woodlands. The best flowers are produced from bulbs planted 4 inches to 5 inches deep, a rule that applies to most bulbs, *Crocus* excepted, as the latter succeed best about two inches in depth. *Galanthus Elwesii*, the giant form of *nivalis*, is not adapted for woodland planting unless the soil is of fair depth, but it attains its full development in good garden soil, and is most at home in borders or on the rock garden. The interval after *Scilla bifolia* flowers is occupied by the *Chionodoxas*, of which three varieties are admirably adapted for naturalising, namely, *Lucilia*, with rich blue flowers and white centre; *sardensis*, pure gentian blue flowers;

and gigantea, with large flowers of lavender blue. Greater attention might be given to Muscari at this season, as they require no special soil or attention, and when naturalised on grassy banks, beside walks, on rock gardens and similar positions they practically look after themselves. Heavenly Blue is the best variety for large effects, as it is both vigorous in growth and lasts long in flower. All the forms of Muscari botryoides and such species as comosum, neglectum, paradoxum and plumosum are admirable in short grass, while the large, fragrant Musk Hyacinth (*moschatatus majus*) should be specially accommodated on the rock garden.

Few bulbous plants yield richer effects or are more permanent in their results than Narcissi. A few Narcissi that succeed best in grass are obvallaris, spurius, moschatus of Haworth, pallidus præcox and scoticus. Several of these are species and natural hybrids, and do not readily accommodate themselves to cultivated ground. A choice Narcissus to grow in grass is W. P. Milner. It is a dwarf variety, with large, elegant, sulphur-coloured trumpets slightly pendulous in habit, while of somewhat similar habit is Johnstonii Queen of Spain, with lemon yellow trumpets of exquisite grace; indeed, it is one of the most beautiful of all Narcissi when grown in grass. The Poet's Narcissus also succeeds in grass. The bright red cups and snowy perianths form a most acceptable contrast to the general run of yellows, while their fragrance is not the least of their charms. THOMAS SMITH.

Coombe Court Gardens, Kingston Hill.

THE GREENHOUSE.

NOTES ON ORCHIDS.

COOL-HOUSE ODONTOGLOSSUMS.

THE **T**HE Odontoglossums are the most popular among cool-house Orchids, especially the variable *O. crispum*, which is always admired whenever seen on account

of its refined beauty and its usefulness as a decorative subject, either as button-holes, for arranging in vases, or when left on the plant.

There are both pure white and spotted forms, the first-named being held in high esteem by Orchid fanciers. Other species embrace *harryanum*, *Pescatorei*, *luteo-purpureum*, *Hallii* and *triumphans*, while the hybrids are almost legion. The various kinds of *O. crispum* have been employed by the hybridists, with grand results, while the same remarks apply to such as *Pescatorei* and *harryanum*. A few of the most attractive hybrids are *Rolfæ*, *ardentissimum*, *amabile*, *percultum* and *Phebe*.

Cultural Hints.—A suitable structure for Odontoglossums is one having a low span-roof, preferably running from north to south. Two stages are needed, one near the hot-water pipes, which is covered with finely-broken coke or shingle, and the other, usually a movable one, placed on bricks or inverted flower-pots, so as to bring the plants within the desired distance of the glass. This top stage can be made of ordinary wooden battens, left unpainted, when it retains the moisture for a much longer period. Both top and bottom ventilators must be provided, and a tank for

storing rain-water is essential, while, of course, roller blinds are a necessity, because all Odontoglossums—and Orchids in general—are shade-loving subjects. At one time it was the general rule to allow the temperature of the Odontoglossum-house to fall rather low during the winter months, but it has been proved that an average temperature of 55° to 60° Fahr. gives much better results. When the weather is frosty, however, a few degrees lower is less harmful to the inmates than excessive fire-heat. Throughout the greater part of the year a little air, both top and bottom, may be left on day and night, the exceptions being during very cold weather and when the division is vaporised for insect pests. A moist, buoyant atmosphere must be created by damping down the stages, floors and walls, say, twice or thrice each day, according to the elements outside; but in winter this must not be overdone, or the foliage may become disfigured and the tips decay.

decayed Oak leaves and sphagnum moss in equal parts. The whole is cut up fairly fine, all the dust is sifted out, and, when the ingredients are thoroughly mixed, it is ready for use. Ordinary flower-pots are selected and filled one-third of their depth with clean, broken potsherds for drainage. When the repotting operation is completed, the plants are arranged in a batch at the warmest end of the house, where they can receive special attention in regard to damping down and watering, for an overdose at this period would be detrimental to the future welfare of the plant. As growth and root action advances, the supply of water can be increased till the pseudo-bulbs are fully developed. After the completion of growth the amount of water necessary is naturally less, and at no time ought the plants to suffer from lack of moisture at the base to such an extent as to cause the bulbs to shrivel. Thrip is the worst insect enemy, but this can be kept in check by vaporising

DRY RETAINING WALL IN THE ITALIAN GARDEN AT GARSTON PARK, GODSTONE.

Repotting the Plants.—Where a quantity of Odontoglossums are grown, a few plants will need repotting at different periods of the year, but the largest number require attention in the latter part of August or early in September, while the collection is looked through again in February for any that were not quite ready, say, in September. Orchids are usually repotted when a fresh hatch of roots are seen at the base of the new growth, and with Odontoglossums they are apparent when it is from 3 inches to 4 inches high. Specimens in a healthy state may be moved into a pot two sizes larger without much disturbance beyond taking away a few of the useless back pseudo-bulbs and any sour soil. All examples are not in such a happy condition, and owing to some error in cultivation, such as over-watering, have lost their roots. When this is the case, a smaller receptacle is generally the rule, for all the old compost and dead roots must be removed.

A good potting mixture is made up of *Osmunda* or *Polypodium* fibre, the best quality peat, partly

the house at intervals with one of the reliable remedies advertised in THE GARDEN. SENTINEL.

ROCK AND WATER GARDEN.

A DRY RETAINING WALL AT GODSTONE.

THE **T**HE low, dry retaining wall, with rough stone steps, shown in the accompanying illustration, is in the Italian garden at Garston Park, Godstone, the residence of Mr. E. W. Blessig. As will be seen, the wall is planted with various kinds of trailing plants, while the Roses on the wall at the back form a suitable setting to the more lowly vegetation. The clock-tower was removed from St. Mary le Poer Church, Old Broad Street, London, E.C., when the church was demolished in 1907, and was erected in its present position by a former owner of Garston Park. It bears the inscription "John Thwaites 1797."

A TULIP FOR THE ROCK GARDEN.

(*TULIPA PRIMULINA*.)

Now that the autumn is here, we must decide what bulbs we shall buy to extend the beauty of our alpine garden. While Narcissi, Galanthus and the many species of Crocus are frequently seen, the various species of Tulipa are not so often noticed; and while to a certain extent formal in their shape, they make a delightful patch of colour amid the cushions of the alpine plants. Among the few species which I have grown, some stand out more forcibly than others, possibly because of the contrast they happened to make with other plants at the moment of flowering, rather than that they were really more praiseworthy than many of their kindred.

Certainly the brilliant yellow cups of Tulipa persica clusiana, with their rich golden bronze reverse, make a charming picture, and are

eye than in the case of *T. persica*, and if planted among some dwarf Sedum, such as *S. album*, or one of the looser-growing Mossy Saxifrages, the foliage as well as the flowers will be kept clean from splashing soil. I find they take very kindly to a compost of loam, leaf-mould and sand, worked into the already gritty soil of the rock garden, while they are very accommodating as to aspect, provided they are somewhat sheltered from driving winds, which are liable to bruise the flowers. REGINALD A. MALBY.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Harvesting Carrots.—There can be no doubt as to the importance of these roots during the

of quality and flavour, and those who want Parsnips in perfection must store in the beds where they have grown and draw for use as wanted. This involves covering the bed so effectually that it is impossible for frost to enter sufficiently to entirely stop digging. Spread on hay, straw, Bracken Fern—in fact, anything that may be at command, and see that the covering is equal to any demands that may be made upon it. It is wise to secure enough roots for one week each time that lifting is in hand. There will not be much loss in that time.

Winter Greens.—There can scarcely be any doubt that in some soils and situations the several kinds of green vegetables, which are of such inestimable value during the winter months, have grown more freely than is altogether desirable, for it has brought them into that condition of luxuriance which gardeners are heard to designate as "proud"—too proud, in fact, to withstand the vagaries of our peculiar weather. We cannot afford to lose them, so we must endeavour to check their progress, and it will commonly be found that treading hard round the stems when the soil is on the dry side will do all that is necessary in that direction. Alike to favour tidiness and good health, all yellowing leaves should be removed from Brussels Sprouts.

Dandelion Salad.—The day is rapidly approaching when we shall all want Dandelion salad in the winter months, and no one need find it difficult to provide. Seeds sown in thoroughly-prepared ground in April, the seedlings thinned as required to leave the plants ample space, and all weeds suppressed will ensure strong roots, which can be lifted at the same time as Carrots and Beetroots in the autumn. These are packed closely together in deep boxes with a little soil between them, and placed in a dark, warm, moist place. In a short time yellowish green leaves will push up, and it is certain that those who consume them will add a dainty salad to their dietary, and one that will render excellent aid in keeping them in good health.

Late Potatoes.—The lifting of Potatoes still in the ground must be pushed forward with all possible speed. It is much to be feared that every variety will be seriously diseased, and no efforts must be spared to store the tubers quite dry and with every suspected specimen removed. Where spraying was adopted during the growing season the tubers are much sounder, though the almost continuous rains of that period prevented the mixtures doing as much good as they would have done in a drier season. In any case do not store in larger heaps than is absolutely imperative, and spare no efforts to examine the whole of the stock at frequent intervals. Violent heating in big heaps helps the disease to spread, and if no inspection is made it is quite conceivable that the whole of the crop will become a mass of diseased tubers. Admit plenty of fresh air to the storehouse, but strenuously guard against frosts, as they will instantly spell ruin. H. J.

A COLONY OF *TULIPA PRIMULINA* IN A SMALL ROCK GARDEN. BULBS MAY BE PLANTED NOW.

sufficiently dwarf—about 4 inches or 5 inches—to place close to the eye. Tulipa Greigii, too, hailing from Turkestan, makes a splendid splash of colour, as its goblets of brilliant orange scarlet, spotted on the inside, rise from their handsome leaves. With me, however, this has not proved too robust, flowering less freely than others. Perhaps I have been unfortunate, or did not give it the best position.

One of the most effective and daintily-coloured of this lovely family, and one which flowered remarkably well with me last spring, was Tulipa primulina, or, to be more exact, *T. stragulata primulina*. The flowers are of a soft primrose yellow and very beautiful in form, while the foliage is of a delicate glaucous green. A group of these suitably placed in the alpine garden is most attractive.

As their height is 12 inches or thereabouts, they can be employed somewhat further from the

winter months, when the change of vegetable food is none too abundant even in the best gardens, and the grower must spare no efforts, beyond the production of the crop, so to preserve it that the utmost value is secured. This spells care in storage, and no untidy heaps will satisfy. No root must be broken or bruised in lifting, and nothing beyond the roughest of the soil ought to be removed. Then in a suitable outhouse, cellar, or other place build up neat, square heaps of alternate layers of Carrots and sand or fine, dry soil. Here the roots will keep quite plump, retain the whole of their flavour, and are easily procurable whenever a supply may be required.

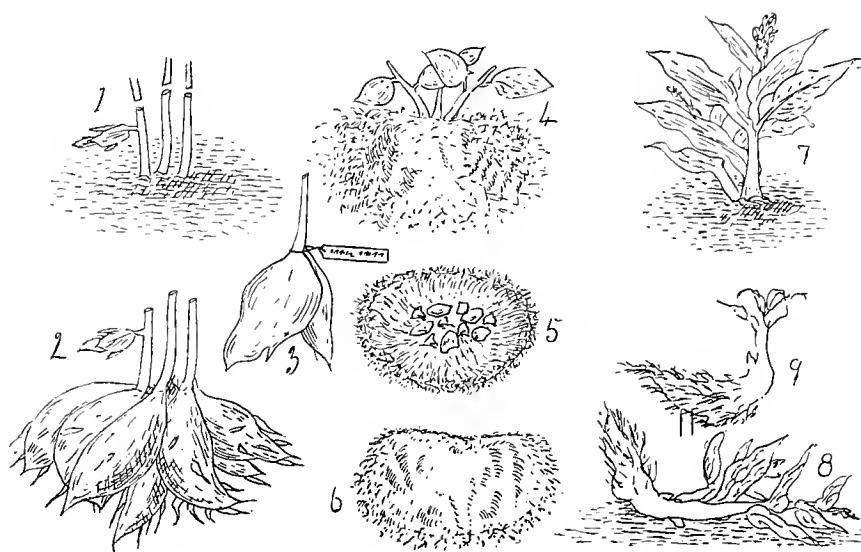

Parsnips for Winter.—It is regretted that Parsnips cannot be satisfactorily wintered in a manner identical or similar to that adopted with Beetroots and Carrots. The fact, however, remains that no matter what material is utilised for storage or where the heap is located, there is marked loss

GARDENING FOR BEGINNERS.

HOW TO STORE DAHLIAS, BEGONIAS AND CANNAS.

ALL these can be safely stored through the winter months by amateur cultivators who only possess primitive means for the keeping of such plants. A high temperature is neither necessary nor desirable, and some, owing to inexperience, spoil good produce through subjecting it to an unsuitable temperature. A very moderate temperature—with, of course, safety from frosts—dryness and freedom from cold draughts are essential points to observe. The Dahlia and Begonia are both very soon damaged by frosts, and the last-named may be lost through placing the tubers too close to hot-water pipes and under a drip from a plant stage.

The early frosts, which blacken the leaves of Dahlias, do not, as a rule, injure the tubers, but it is always better to take up the latter before any frosts affect the tops. The first thing to do is to make the name labels secure to the stem just above the ground, then cut off the tops about one foot from the soil-level, as shown at No. 1. The soil must be removed far enough away, so that the tubers will not be damaged by the spade and fork used. No. 2 shows a cluster of tubers properly lifted; and No. 3 a younger tuber with the label properly attached to it. No. 4 denotes a Begonia tuber as lifted from the soil; No. 5 shows the crown of the tuber with the leaf-stalks removed when well ripened; and No. 6 shows the same tuber cleared of surplus soil, and ready for storing in dry fibre, sand or soil in shallow boxes. No. 7 shows a Canna plant ready for lifting; No. 8 the same plant laid on a dry base to dry—the plants should be laid in rows on the floor of a shed and the root portion covered with mats until the leaves have shrivelled a little; and No. 9 shows the same root ready for storing in sand, soil or fibre in sheds. No. 10 shows a cluster of Dahlia tubers simply covered with straw. This is the wrong way to store them, as frost may penetrate the straw. Another wrong way to store is shown at No. 11. Begonia tubers in boxes placed so close to the hot-water pipes are sure to be lost through decay.

HOW TO LIFT DAHLIAS, BEGONIAS AND CANNAS FOR STORING.

How to Store.—Dahlia tubers are safe if stored in sand, as shown at No. 12, in a dry shed. Frost is excluded, and fungus will not grow round the crowns of the tubers. No. 13 shows how to arrange Begonia tubers in shallow boxes filled with sand or fibre. These boxes may be placed on shelves in a fruit-room or any frost-proof shed, as shown at No. 14. It is best to store Cannas underneath, also Dahlias, as shown at Nos. 15 and 16 respectively. Where walls face the north it is a good plan to put some straw against the wall to protect the roots, as shown at No. 17. The straw (No. 18) must be well padded against the wall.

The wrong way to trim Cannas and Dahlias is denoted by the sketches Nos. 19 and 20 respectively. If the stems be cut off while rather green close to the tubers, there will be a considerable weakening of the latter at once, and, later on,

possible decay of the tuber. In some cases it may be found desirable to divide some of the roots, and where this is done the wounds made must be allowed to dry up nicely before the parts are covered over with soil, sand or fibre. A close-fitting covering is better than a loose one, such as is formed by straw or Fern, but dry straw or Fern may be put on in addition to the sand or fibre with advantage in cases where sudden severe frosts occur.

G. G.

HOW TO POT SPIRÆAS, DEUTZIAS AND DIELYTRAS FOR FORCING.

It is because every plant has to be so carefully handled and treated right from the time of potting to the flowering stage that we value them so highly. There is another reason, a not unimportant one either, namely, the general scarcity of flowers at the time the forced ones are in bloom. The work of potting, watering and forcing of these plants is a very interesting one also. The clumps of Spiræas, both those lifted from our own borders and purchased, should possess prominent crowns, and the same remark applies to the clumps of Dielytras. It is not necessary to use very large pots; if the latter are big enough to contain the root and a small quantity of soil they will do nicely. Loam and leaf-soil in equal proportions, with plenty of sand added, will make a suitable compost. As great quantities of water will be necessary later on, it is an important matter that plenty of drainage material be put in and well placed. Until required for forcing gently, keep the newly-potted roots in a cold frame, or plunged in a bed of ashes outside. Deutzia plants have fibrous roots, and if some soil adheres to them so much the better. Rather more loam must be used in the compost for Deutzias, and firm potting should be the rule. After giving one watering to settle the soil, it will not be necessary to give more than is sufficient to maintain the soil in a medium state of moisture. Deutzias should not be forced too early in the season, especially those plants that have been lifted from the open border.

SHAMROCK.

RIGHT AND WRONG METHODS OF STORING THE ROOTS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Dahlias.—In all probability before these lines appear in print frost will have put an end to the season of flowering of these popular and invaluable autumn-flowering subjects, and those varieties that are required for next season must be lifted and the tubers preserved during the winter months. The growth should be cut down to within 5 inches of the base, and the roots carefully lifted and placed in a cool but frost-proof shed, where they may be kept dry and be examined occasionally. A little dry soil may be worked in among them; but this does not really matter. Tie the label of each variety securely to the remaining growth. This will prevent much confusion.

Spring Bedding Plants.—As soon as the summer occupants become frosted or fail to be attractive, have the plants cleared and the beds well dug and prepared for such subjects as Wallflowers, double Arabis, Alyssum and Myosotis for the spring display, so that these may become firmly established before winter sets in. Avoid planting too thickly, as if all goes well they will grow before flowering in the spring, and splendid effects may be obtained by planting suitably-coloured Tulips and Hyacinths between the plants.

The Rock Garden.

Aubrietias.—The cuttings of the numerous and beautiful varieties will now be found to strike readily if inserted in pots of sandy soil. Their freedom of flowering commends them to all lovers of alpine flowers, and included among their colourings may be found a shade to meet almost every taste. A few of the best are Lavender (a beautiful shade, as the name implies), Moerheimi (a lovely pink), Dr. Mules (a most profuse and persistent flowerer), Pritchard's Ar and Fire King.

Iberis gibraltarica.—For spring flowering on the rockery or edging to the borders this is an excellent and beautiful plant, and the stock may be easily increased at this season by cuttings, which will root readily, as will also *I. corææfolia*, with its masses of pure white flowers.

Sedum spurium splendens.—This is a charming late-flowering Sedum that is making a brilliant display, and well worthy of inclusion at this season.

Plants Under Glass.

Browallia speciosa major.—This is an exceptionally useful plant for the greenhouse at this season of the year, and for those who admire blue and its shades is indispensable. During the plant's season of growth it likes a slightly warmer temperature, but, like many others, when flowering these last much longer when allowed to expand under cooler conditions. Plants are easily raised from seeds, or may be perpetuated by cuttings taken after flowering.

Lily of the Valley.—The forcing of retarded crowns is quite an easy matter where one has the command of fire-heat, and they may be brought along in very quick time. These, after potting or boxing, are best covered over with a little moss and kept in a subdued light for a few days, keeping them well supplied with moisture.

Fruits Under Glass.

Strawberries.—The plants for forcing must be wintered in a convenient place where they are easily got at for forcing in batches later on. Much will depend on the weather experienced, and no hard-and-fast rule can be laid down as to when these should be packed away. The pots should be well packed in leaves or ashes to protect them from frosts, and, if possible, a cold frame given up to them where they can have protection from heavy rains. The plants should, of course, be placed on a firm basis, preferably cinder ashes, to prevent worms entering the pots.

Late Melons.—To finish these well requires a considerable amount of judicious care and attention as regards airing and watering. The use of manures should be very cautious, it being far better to finish smaller fruits than those larger and less flavoured. Give air at all favourable opportunities and in plenty, with a circulation of heat when the fruits are ripening and less moisture in the house, withholding water at the roots.

The Hardy Fruit Garden.

Peaches and Nectarines.—These are fruits that a great many owners of small gardens would

like to possess, and where a suitable position can be afforded them, and also protection given when in flower, with periodical attention to the trees' requirements, such as disbudding the foliage, thinning of the fruits and feeding, excellent fruits may be obtained, especially in a season such as the last. But unless the trees can be given this attention, I would urge amateurs to leave their culture alone. As soon as the leaves are off, or even before, any transplanting, lifting or root-pruning that is necessary may be carried out. Young trees that have carried no fruits are apt to make much too gross a growth, and the latter treatment will do much to improve them.

The Shrubbery.

Transplanting.—Though it seems somewhat early, the work of transplanting, especially of many of the evergreens, may be proceeded with at once, and with the continuous rains experienced this season the shrubs should move well. A rule which applies to all planting, whether fruit trees or anything else, is to have the hole sufficiently large, as nothing will check growth more than cramping the roots. Where planting of large subjects has to be done, the holes may be prepared at any time, and these form excellent places to bury leaves and other rubbish.

The Kitchen Garden.

Endive.—Continue to prick out into cold frames the seedlings that were sown last month. Lift the plants growing out of doors, and plant closely together in cold frames to blanch.

Lettuce.—This requires similar treatment, with the exception of the blanching. Ventilate the frames freely, so that the plants do not damp off.

Salsify and Scorzoner.—Where these vegetables are grown, the crop will by now have completed growth, and if the space is wanted, lift and store in sand or ashes.

Onions.—One of the best methods of storing Onions where space is limited is that known as roping, as the bulbs are easily got at when required, are exposed to the air, and are portable. Some local shows provide a class for the best rope of Onions, and it is an interesting feature. Whether intended for exhibition or no, the bulbs should be graded and placed in their sizes accordingly.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Montbretias.—As a rule it is best to lift these. They may be safely preserved if buried deeply by the side of the wall of a building—so deep that frost cannot reach them—especially if straw is heaped over them when hard frosts supervene. If any are planted at this time, see that the corms are 6 inches below the surface, and add some protecting material over all.

Herbaceous Borders.—As soon as the bulk of the flowers are over, these should be rearranged, either in whole or in part. Quite a number of plants succeed best when treated as annuals—that is, broken up and replanted every autumn or spring. The labour and rearranging are much lessened and simplified if the planting follows closely on the cultivating of the ground, and this method has the added advantage that wet, should rain fall, does not stop planting, as is the case when the freshly-worked soil gets saturated previous to replanting.

How to Plant.—Everyone has his or her own method of arranging, but the great majority of plants produce a superior effect when planted in small pieces and set close together, rather than large sets and wide apart. It is not easy for the inexperienced to credit and work upon this, but there is nothing more certain. Some plants, e.g., *Kniphofias*, if lifted do better not divided, unless very large, and others, e.g., *Statice*, *Helleborus niger*, the *suffruticose Candytufts*, *Japanese Anemones*, *Irises* generally, *Trollius* and *Astilbes*, are better if left undisturbed for a long series of years.

Weedy Perennials.—There are some, on the other hand, which extend so rapidly and persistently as to become weeds. *Senecio tangenticus*, some of the *Asters*, *Bocconias*, *Solidagos* and *Helianthus* are examples. They can hardly be dispensed with,

and the only way of keeping them within due bounds is to dig up the plants carefully before cutting over the stems and replanting with care, in early summer rooting out any pieces that have been overlooked just now.

Planting Bulbs.—If the ground is in good condition, much labour, in at least some kinds of soil, is saved if the ground is merely eased up with a fork, some rotten manure having previously been spread over the whole surface, and the ground, if dry enough, lightly pressed with the foot. The manure gets well mixed with the soil in planting either bulbs or plants. Plant rather close so as to have an even bloom. A thick dressing of soot when the planting is finished will be serviceable in hindering blackbirds from working among the soil. It also forms a very effective manure.

The Vegetable Garden.

Seakale.—Some Seakale crowns may be lifted, rested by lying for ten days or so exposed, then trimmed of roots and placed among damp leaf-soil in a box, to be covered and placed in a hothouse. The crowns are sometimes difficult to start at this season, but the drying and, subsequently, a high temperature induce growth.

Rhubarb.—A number of roots may be placed in the Mushroom-house, where they will continue throwing up stems for many weeks. I merely keep the roots moist, and place no soil or other material about them. A fresh plantation may be made now by division of the old roots, or from seedlings. Dig the ground—or trench it is better—giving about three-quarters of a ton of cow-manure to each square rod. Plant 4 feet to 6 feet apart.

Horse-radish.—Roots to last the winter may be lifted at any time, and preserved for use in a shed and covered with sand. Either now or later a fresh plantation may be made, trenching the ground 2 feet deep and inserting short pieces of the roots 10 inches below the surface. This can be done as the work proceeds. The growths come up as straight as an arrow, which material planted near the surface cannot be depended on making. Manure is not of importance for this crop, and if difficult to obtain, none need be added to the soil.

The Plant-Houses.

Cinerarias.—If frames are in a position where frost strikes them, it would be as well to transfer the plants to a pit or other suitable structure, but they succeed so much better in cold frames that they should not be removed thence until it is unsafe to leave them longer. A cool bottom should be given them in the pit, such as stone or gravel, in preference to standing them on a wooden trellis. Manure-water at regular intervals will be appreciated.

Roses.—Young plants of Dorothy Perkins, *Hiawatha*, &c., growing in borders may now be lifted and transferred to pots for spring flowering. If placed in a glass structure at once, let it be a perfectly cool one, when roots will be produced without the buds being excited, but the plants will do perfectly well in the open, the pots meanwhile being plunged in some moist material. Roses trained in houses may be pruned now, thinning out all weakly material incapable of bearing blooms, and shortening the others as little as possible so long as no immature points are left.

The Fruit Garden.

Currants.—Both Red and Black, may now be pruned, and the ground dressed for the winter. A large amount of young wood should be left on Black Currants, as it is mainly on this that the fruit appears. Some growers top the shoots, but, provided a supply of young ones are being thrown up from the base of the bushes, that need not be done. Anyhow, it has a tendency to thicken the shoots unduly and diminish the size of the berries.

Apples.—The root-pruning of trees that have yielded their crop may now be proceeded with. If young trees are properly managed, it seldom happens that when old they need their roots cut. Old trees should have only a portion shortened at one time, and if very old and the roots very thick, only the smaller of these should be cut.

Pears not too old are very susceptible to the influence of root-pruning. The effect on seemingly hopelessly barren trees is extraordinary, the crops in the course of two or three years being very large. Yet the utmost caution must be exercised in the case of old neglected trees, which may be killed outright if severely handled.

R. P. BROOKERSON,

Tynningham, Prestonkirk, —N.B.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Pyrus veitchiana.—A new species from China and exhibited for the first time. The plants were of rather tall, spreading, diffuse habit, with Nut-like leafage and dark woody stems bearing axillary clusters of roundish crimson fruits. Judged by these examples, the plant should prove highly ornamental.

Cotoneaster bullata.—A diffuse-habited plant of rather tall growth, bearing crimson berries in bunches from the nearly horizontal or slightly drooping branches.

Berberis stapfiana.—This new species is of erect, bush-like habit and, as shown, about three feet high and through, the branches being freely furnished with spines and rather thickly set with light coral red fruits. These three novelties were exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

Aster Nancy Ballard.—This is one of the semi-double-flowered Michaelmas Daisies, and is calculated to become one of the most popular by reason of its neatness and the warmth of its rosy mauve flowers. It is of medium height and produces handsome panicles of flowers. Exhibited by Mr. Ernest Ballard, Colwall, Herefordshire.

Chrysanthemum Mrs. Lloyd Wigg.—A large and handsome variety of the drooping-petalled Japanese type, and clear canary yellow in colour. From Messrs. William Wells and Co., Limited, Merstham.

Chrysanthemum ...—A so-called single that is bound to be in demand because of its colour—a rich gold and yellow. The variety, too, is possessed of a sturdy habit of growth, a short peduncle, and is generally well set up. Exhibited by Messrs. Cragg, Harrison and Cragg, Heston, and by Messrs. Wells, Limited, Merstham.

Cotoneaster Zabelii.—A tall and rather thin-habited species whose branches are furnished with berries of a dull red or deep crimson shade.

Cotoneaster salicifolia rugosa.—A brilliant and striking plant of considerable worth and ornament. Tall and spare of habit as exhibited, it is still freely furnished from the main stem with yard-long, slightly drooping and slender branches, which are freely endowed with clusters of scarlet fruits throughout the greater part of its length; hence it is as distinct as it is beautiful and ornamental. These two novelties were from the gardens of the Hon. Vicary Gibbs, Elstree.

Adiantum cuneatum micropinnulum.—The varietal name here is somewhat descriptive of one of the most elegant and beautiful Ferns we have seen. In effect it is an *Adiantum cuneatum gracillimum* whose pinnules have been reduced to the last degree of fineness. The red-tinted fronds of youth add to the many charms of an exceedingly graceful variety. From Messrs. H. B. May and Sons, Edmonton.

NEW ORCHIDS.

A first-class certificate was awarded to *Cattleya harrisiana*, shown by C. J. Phillips, Esq., The Glebe, Sevenoaks. It is a handsome hybrid, with white sepals and petals and a brilliant ruby purple lip. Parentage: *C. Fabia alba* × *C. Warszewiczii* Frau Melanie Beyrodt.

Awards of merit were granted to the following: *Cattleya hardyana* Herbert Goodson, from H. S. Goodson, Esq., Fairlawn, Putney; *Miltonia*

Harwoodii, from Sir Trevor Lawrence, Bart., K.C.V.O.; *Cattleya Mrs. Pitt* Charlesworth's variety, shown by R. C. Doux, Esq., Marfield, Liverpool; and *Odontioda Charlesworthii* Orchid Dene variety, from Messrs. J. and A. McBean, Cooksbridge.

All the foregoing were shown before the Royal Horticultural Society on the 8th inst., when the awards were made.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 29, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PHLOXES (Miss E. A. H.).—Without seeing specimens of the disease we could not say what is amiss, though from the suddenness of the failure it might be due to stem-eelworm, and if so, your only remedy is to cut down and burn all affected parts. Wireworm, if present in the soil, might also be responsible for the mischief, and if so, the bored stems should afford the proof.

MIGNONETTE (M. D.).—Your Mignonette is attacked by a fungus at the root. Fungi are, as a rule, greatly encouraged by the presence of an acid soil, and Mignonette, on the contrary, delights in lime-rubble. We have, just where we are writing, one of the finest beds of Mignonette we have ever seen, growing in mortar rubbish and a little sandy soil. You would probably have better success if you had some lime-rubble mixed with the soil in which you are going to sow your Mignonette another season.

PHLOXES FAILING (M. C. L.).—The failure has been brought about by stem-eelworms, and the only thing to be done in the circumstances is to collect all the affected parts and burn them. This is the more necessary, since the pest is likely to be perpetuated from year to year through the medium of its eggs, as these continue in the soil and in due course gain entrance to the stems of the plants. The soil should be treated with sulphate of potash at the rate of 1 lb. to 12 square yards or 15 square yards. A few months later a further application might be given, first stirring the soil well.

TREES AND SHRUBS.

POTTING VALLOTA LILIES (F. G. W.).—The best time to repot *Valloa* Lilies is immediately the flowers are past. Annual repotting is, however, by no means necessary, providing the roots are in good condition; indeed, when in that state they will stand for two or three years without being potted. *Valloas*, in common with other bulbous plants, will flower freely when the bulbs are tightly packed together in the pot. At the least sign of decay about the roots they should, however, be repotted.

BLUE HYDRANGEAS (T. S. and N. L.).—In some soils *Hydrangeas* turn blue, while this tint is often produced artificially. It is generally assumed that the presence of iron in the soil is the cause of the change, and this has been borne out by numerous experiments. When grown in pots, one of the most successful methods of treatment is to thoroughly mix about a tablespoonful of sulphate of iron with each peck of soil. Then, in addition, as the pots get full of roots, put a pinch of it in the water about twice a week. Refuse from the blacksmith's shop is sometimes mixed with the soil, but it is less satisfactory than using the sulphate. Alum-water has also been used to induce the required blue colour. The alum should be given at the strength of 1 oz. to each gallon of water. To prepare the alum, it must first be crushed and dissolved in a little hot water. This should be given directly the flower-buds are visible, watering the plants with it at intervals of eight or ten days, and discontinuing it when the flowers open. It must never be given when the roots are very dry. A liberal quantity of lime in the soil is against obtaining the required blue colour. We have just heard of a Continental preparation for making *Hydrangeas* blue. It is called Cyanol, and can be obtained from horticultural sundriesmen. We have not tried it ourselves, but know where it has given satisfaction.

ROSE GARDEN.

BORDER AND ROSE-BED (Enquirer).—With regard to the portion intended to be devoted to Roses, the idea of an addition of clay soil is good, provided that you intend to incorporate this with the staple soil. Our advice for the entire border would be to give a 9 inch dressing of the clay throughout, allow it to lie exposed to the action of air and frost for some weeks, then deeply trench the whole, and break down and incorporate the clay as the work proceeds. After trenching add burnt refuse from the garden rubbish fires, and after the lapse of a month retrench the whole and add well-decayed manure freely. In this way you would secure a permanently useful soil, together with a liberal addition of lime present in the clay, and of which your present soil stands much in need. With the second trenching completed, you might plant the Roses at once, or you might leave the planting of the whole border till the turn of the year.

REMEDY FOR BLACK SPOT (S. M. B.).—We wish we could help you; but, unfortunately, there seems to be no remedy for this disease. We really believe it is largely imported from the Continent, for we know whole fields are defoliated by the pest in some seasons. If you could transplant your Roses to a new site, or have the bed-overhauled this autumn, you might get rid of the pest, and unless the plants are old we should strongly advise this plan. By trenching deeply and burying the surface soil you would largely destroy the fungus; then in spring commence early and continue to spray throughout the summer with Cupram, which is a preparation of carbonate of copper dissolved in ammonia; or, if you cannot obtain this, spray with Bordeaux mixture.

ROSE FOLIAGE BLIGHTED (I. C. E.).—The foliage you send is badly attacked with mildew, a disease or fungus very much in evidence among Roses at this season of the year. It can be kept in check, if not entirely subdued, by timely spraying with V2 K Fluid or Jeyes' Horticultural Wash, and for both we would refer you to our advertisement columns. Often these rambles suffer from drought. We look after other Roses, but too frequently these are neglected. We should advise you to cut off the badly-diseased shoots and burn them, then give a good spraying with the wash. Also fork around the plants and give each of them four or five gallons of water, repeating this once a week if the weather continues dry. Some liquid manure would also be helpful, but it is best to apply the plain water first.

ROSE FOLIAGE DAMAGED (P. H.).—As you have not sprayed the Roses, we cannot attribute the damage to the insecticide, although at first sight we were disposed to do so. There must be something in the soil or air to cause such damage. Have you any chemical works near you? Or have the plants had too strong a dose of some chemical? We should advise you to dig a plant up and examine its roots. If the fine roots are quite white they are all right. There is, unfortunately, such a tendency to make up Rose-beds containing all sorts of chemicals that the wonder is so few of the plants fail. Perhaps you can furnish us with some particulars as to the making of the beds. In the meantime cut off this scorched foliage and cut back the growths to good strong eyes. Keep the soil well stirred and refrain from artificial watering for a time.

ROSES FAILING (P. H.).—There was very careless preparation adopted as regards the plants, for they had been planted without pruning their roots. It is always advisable to trim these back rather considerably before planting. Evidently the soil is not at fault, for you say some of the plants are sending up nice shoots now. We fear there is great carelessness adopted by some growers when they despatch the plants in not taking sufficient care of the roots. These should always arrive in a moist condition, and most up-to-date Rose-growers see that this detail is attended to. We advise you to look carefully into this matter when planting again. On trimming the roots they should be quite white when cut, and should have a sort of fleshy appearance. You can soon detect by this if the plants are healthy. If they are dry and shrivelled, we should refuse such plants.

MISCELLANEOUS.

NAMES OF PLANTS.—*F. M., Workshop.*—1, *Quercus nigra* (Water Oak); 2, *Q. Phellos* (Willow Oak); 3, *Pyrus torminalis* (Wild Service);—*Hamish.*—1, *Asplenium Filix-foemina cristatum*; 2, *A. B., Northumberland.*—1, Maltster; 2, Dutch Codlin; 3, Flanders Pippin; 4, Cox's Pomona; 5, Lemon Pippin. —*G. J. B.*—1 and 2, Bismarck; 3, King of the Pippins; 4, Ross Nonpareil; 5, Hawthornden; 6, Cobham; 7, Flanders Pippin; 8, Vicar of Winkfield.

SOCIETIES.

EXHIBITION OF BRITISH-GROWN FRUIT.

From the standpoint of popularity among professional gardeners and market-growers, the annual exhibition of British-grown fruit is the best the Royal Horticultural Society holds at Vincent Square. The display on Thursday and Friday of last week, though not quite so extensive as usual, was of exceptionally good quality throughout, and proved that first-class fruit can be grown in seasons as unfavourable as the past has undoubtedly been.

In the class for the Affiliated Societies' Challenge Cup, for six dishes each of cooking Apples, dessert Apples, and dessert Pears, distinct, six fruits to each dish, there were four entries, the first position being won by the Ipswich Gardeners' and Amateurs' Association. The Pears here were exceptionally good, and the dishes of Apples Ribston Pippin, King of the Pippins, Cox's Orange Pippin, Peasgood's Nonsuch, Charles Ross and Bramley's Seedling called for special mention. Second prize went to the East Anglian Horticultural Club, which won the challenge cup last year. The Pears here were even better than those in the first-prize collection, but the Apples were not quite so well coloured. Annie Elizabeth was, however, a superb dish. Third honours went to the Colchester and District Gardeners' Association, Pitmaston Duchess Pear and Cox's Orange Pippin and Newton Wonder Apples calling for special mention. The challenge cup was awarded to the Colchester Association as Ipswich and East Anglian have won it during the last three years.

DIVISION I.

Open to Gardeners and Amateurs Only.

For a collection of nine dishes of ripe dessert fruit there were four superb collections, Lady Henry Somerset, Eastnor Castle, Ledbury (gardener, Mr. G. Mullins), being placed in the coveted first position with an almost perfect collection. Grapes Muscat of Alexandria and Gros Maroc, Countess Melon, Charles Ross Apple, Pineapple Nectarine, Peaches Late Devonian and Barrington, and Doyenné du Comice and Pitmaston Duchess Pears were other items shown. These were in every way admirable. Second, the Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), whose weaker bunches of Grapes told against him for the first place. The finer dishes were Appley Towers Grapes,

THE FIRST-PRIZE COLLECTION OF DESSERT FRUIT IN CLASS 2 AT THE BRITISH FRUIT SHOW.

Peaches Golden Eagle and Solway, Apple Washington, and Pitmaston Duchess Pears, which were very fine. The Peaches and Pears were particularly good and strong in this lot. Third, the Earl of Harrington, Elvaston Castle, Derby (gardener, Mr. J. H. Goodacre), whose Golden Eagle Peaches and Washington Apples were very fine.

For a collection of six dishes of ripe dessert fruit there were six entries, the leading place being occupied by Lord Belper, Kinaston Hall, Derby (gardener, Mr. W. H. Cooke), whose best dishes were bunches of Gros Colmar Grapes, fine in berry and well finished; splendid Gladstone Peaches, and Charles Ross Apples of magnificent quality (see illustration above). Second, Lord Hillingdon, Wildernesse, Sevenoaks (gardener, Mr. Shelton), whose Doyenné du Comice and Pitmaston Duchess Pears were very good. Muscat of Alexandria Grapes were also good in this collection. Third, Lord Howard de Walden, Audley End, Saffron Walden (gardener, Mr. J. Vert), who showed some capital dishes of fruits.

For five distinct varieties of Grapes, two bunches of each, the Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), was in the place of honour, his fine examples

being Gros Maroc, Buckland Sweetwater, Madresfield Court and Muscat of Alexandria. The first-named were particularly well coloured. Second, the Earl of Harrington, Elvaston Castle, Derby (gardener, Mr. J. H. Goodacre), with good examples of Golden Queen, Gros Maroc and Muscat of Alexandria. Mr. Charles Beyer, Tewkesbury Lodge, Forest Hill, S.E. (gardener, Mr. E. C. Wickens), was recommended a third prize. There were five collections staged, all of admirable quality. Our sympathies are entirely with the judges' recommendation for a third prize, two prizes in such a class being, in our opinion, altogether inadequate.

For four varieties of Grapes, two bunches of each, Lord Hillingdon, Wildernesse, Sevenoaks (gardener, Mr. J. Shelton), was first, having in his lot two superb bunches of Muscat of Alexandria, which for colour and finish were excellent. Second, Mr. H. St. Maur, Plover Park, Newton Abbot (gardener, Mr. G. Richardson), whose Muscat of Alexandria and Mrs. Pince were of good quality.

For two bunches of Black Hamburgh Grapes, the Rev. W. Beecher, Willow Hall, Newark, was first with good bunches of well-finished berries. Second, the Duke of Newcastle, Clumber, Worksop, whose larger bunches were composed of somewhat smaller-sized fruits. There were half-a-dozen competitors in this class, though the quality shown was not so high as might have been expected.

For two bunches of Mrs. Pince Grape only three competitors came to the front, the first prize going to Mr. H. St. Maur, Plover Park, Newton Abbot (gardener, Mr. Richardson), who had good bunches of well-finished fruits. Second, Mr. G. Miller, Radlett.

For two bunches of Alicante Grapes there were eleven competitors, the place of honour being secured by Mrs. W. G. Raphael, Castle Hill, Englefield Green (gardener, Mr. H. Brown), who had superbly-finished bunches of fruits. Second, Lady Henry Somerset, Eastnor Castle, Ledbury. Third, Lady Tate, Park Hill, Streatham Common (gardener, Mr. W. Howe).

Two bunches of Madresfield Court Grapes: First, the Earl of Harrington, Elvaston Castle, Derby, who showed well-finished bunches of fruits; second, Lord Savile, K.C.V.O., Rufford Abbey, Ollerton; third, the Duke of Newcastle, Clumber, Worksop. In this class the prize-winner in the second place had much the largest bunches, but they were not so well finished as a whole. Obviously size of berry and fine finish, and not big bunches, carry the greatest weight with the judges.

For two bunches of Grapes Prince of Wales, Lord Savile, K.C.V.O., Rufford Abbey, Ollerton (gardener, Mr. J. Doe), was in the first place with superb bunches of fruits, handsome in the highest degree. Second, Mr. H. H. König, Blundley Heath.

For two bunches of any other black Grapes there were thirteen competitors, the first prize going to medium-sized, well-finished bunches of Appley Towers from Mr. J. Liddell, Sheffield Manor, Basingstoke (gardener, Mr. R. J. Leamouth). Second, Mrs. W. G. Raphael, Castle Hill, Englefield Green, who had Lady Downe's. The Duke of Newcastle had some huge bunches of Trebbiana, and Lady Henry Somerset fine examples of Gros Maroc. We think so popular a class is deserving of more than two prizes.

For two bunches of Muscat of Alexandria Grapes there were eleven entries. Mr. W. W. Mann, Ravenswood, Bexley (gardener, Mr. J. Simon), taking the leading place with finely-finished bunches of fruits. Second, the Right Hon. Lord Hillingdon, Hillingdon Court, Uxbridge (gardener, Mr. A. R. Allan), with handsome bunches. Third, Lady Henry Somerset, Eastnor Castle, Ledbury.

For two bunches of any other white Grape there were eight entrants, Mr. C. A. Cain, The Nod, Welwyn (gardener, Mr. J. Pateman) being first with fine examples of Mrs. Pearson. Second, Mr. W. B. M. Bird, Earham House, Chichester. Third, Mr. Charles Bayer, Tewkesbury Lodge, Forest Hill, S.E. The quality in this class was not of a high standard generally.

A REMARKABLE BASKET OF APPLE WARNER'S KING SHOWN BY MESSRS. GASKAIN AND WHITING AT THE BRITISH FRUIT SHOW IN THE MARKET GROWERS' CLASS. THE LARGEST FRUIT MEASURED 5½ INCHES IN DIAMETER AND WEIGHED TWO POUNDS.

THE GARDEN.

No. 2136.—VOL. LXXVI.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Tobacco Plants and Earwigs.—So many people, particularly amateurs, refrain from growing Dahlias owing to the association of these flowers with earwigs. We have heard lately of a novel way of keeping the dreaded pest at bay. There is something objectionable to earwigs in the Tobacco plant as grown, says a careful observer, and if these plants are interspersed among Dahlias there will be little fear of the presence of this troublesome pest. We give this suggestion for what it is worth, not having experimented in this direction.

Apple Warner's King for Marketing.—The wonderful exhibit of Apples shown in the market-growers' class by Messrs. Gaskain and Whiting of Faversham at the recent show of British-grown fruit provides ample proof, if such were needed, of the excellence of home-grown fruit. The large basket of Warner's King illustrated on page 536 of the issue October 19 was perhaps the pick of this creditable display. We learn that the fruits were gathered from trees sixteen years old, and that 100 trees have averaged 1,500 bushels in the past three years. Twenty-seven of the fruits in the illustration referred to would fill a bushel basket.

Two Useful Greenhouse Flowers.—Two very pretty Abutilons may be seen in full flower at the present time in the greenhouse at Kew, where they occupy positions on the roof. One, Golden Fleece, is a variety of garden origin which is admirable on account of its clear yellow, shapely flowers; these are borne in great profusion over a period of several months. The other, A. insigne, is a species from Colombia which was introduced many years ago, but whose cultivation has been allowed to lapse except in a few gardens. Of vigorous growth, it is admirably suited for the roof of a glass-house, for its lateral branches assume a graceful, pendent character, and the pretty reddish flowers, with their heavily-netted veins, are suspended from long, slender stalks. Both these Abutilons require to be cut back well in spring, so that a good supply of new wood is formed.

A Good Outdoor Chrysanthemum.—Among a number of early-flowering Chrysanthemums that we have grown this year, none has given us more pleasure than a single pink variety. This was sent to us two years ago as a seedling by Mr. D. B. Crane. The plants attain a height of about three feet, branch very freely, and the flowers are produced in great profusion. For cutting it is ideal, a single spray in a vase being particularly pleasing. Our plants have been in flower a month and promise to continue for another fortnight, owing to the fact that the buds do not all open at once. The prominent yellow disc in the centre of the flower is surrounded by a very narrow band of white, the rest of the petals being a pleasing shade of pink. It is

very fragrant. Mr. Crane informs us that he has named it Eric Harvey.

A Useful Rock Garden Plant.—Anthemis Trunfettii is probably the richest-coloured of its set, the golden yellow flower-heads making quite an effective display even so late as mid-September and after a naturally long season of flowering. Dwarfier and superior in every way to A. tinctoria E. C. Buxton, it is a plant to remember for the choice herbaceous border or in the more conspicuous places of the rock garden, where it will be seen to advantage.

Crocus nudiflorus.—This is one of the boldest and showiest in its day of the earlier of the autumn-flowering Crocuses, a species well worthy the attention of those who indulge in grass gardening, or who by hook or by crook could squeeze such things into the quiet, sequestered places of the rock garden. Well established, the large flowers are fully 9 inches or so high, and in reddish violet tones are rendered the more conspicuous by the rich orange stigmata characteristic of this kind. A few of its flowers in sunlight are most attractive.

Waterer's Scarlet Oak.—This Oak (Quercus coccinea variety splendens) is the best of the family for rich autumn colour. It is not only richer in colour, but while some Oaks only colour well in certain seasons, the subject of this note may be relied upon to colour well every autumn. In summer the tree does not differ materially in leaf from the North American Scarlet Oak, but in autumn there is no comparison, the large lobed leaves of Waterer's Oak being much richer and deeper red. As it is a large-growing variety, it is worth considering, as an avenue tree, single specimens in the pleasure grounds, or a group of six to ten trees for effect in the park.

The Cotton Lavender for Dry Banks.—It does not appear to be generally known that the Cotton Lavender (Santolina Chamæcyparissus) is one of the best low-growing plants for clothing dry banks. In such a position it spreads rapidly, and quickly covers a considerable area with a close mass of silvery foliage, while it has the advantage of being very little trouble. Cuttings dibbled into sandy soil in a close frame root with ease, and if planted for one year in a nursery or kitchen garden border, plants quite large enough for permanent planting may be obtained. These, if placed 18 inches apart each way, quickly cover the intervening space, and the only trouble they occasion, for many years is an annual cutting over to encourage young shoots from the base. All the preparation the ground requires for the reception of the plants is to dig it over 9 inches or 12 inches deep if the soil is fairly good, or, if poor, to add a few inches of decayed leaves or manure and then dig it over.

ROGUES IN SWEET PEAS.

SOME IMPORTANT DISCOVERIES.

EVER since the Sweet Pea Countess Spencer was put into commerce, now some ten or more years ago, the question of rogues appearing in Sweet Peas has exercised the minds of those who make it their business to supply the public with seeds, and also those of the public who grow the flowers. Stocks which seedsmen have had perfectly true in their own trial grounds have, the following year, produced a large number of rogues, a fact that could only be partly accounted for. Owing to the widespread and generally-accepted belief that a Sweet Pea flower is always self-fertilised, and that bees or other insects did not effect cross-fertilisation, this question of rogues appearing in what were regarded as true stocks was, as we have already stated, difficult to explain.

In our issue for August 24, page 423, we gave particulars of some investigations which we had made in connection with Sweet Pea seeds that had been grown in California, and stated that we had come to the conclusion, for reasons we plainly set forth, that the appearance of rogues in such well-known and, in ordinary circumstances, fixed varieties as Clara Curtis and Etta Dyke was due to cross-fertilisation.

At the conference of members of the National Sweet Pea Society, held at the Hotel Windsor after the annual meeting on Thursday of last week, this was fully borne out by Major C. C. Hurst, F.L.S., Director of the Burbage Experiment Station, Leicestershire. Major Hurst is a well-known and recognised authority on Mendelism, and has conducted numerous experiments with Sweet Peas as well as with other flowers. In his most interesting paper that he read at the conference he made it quite clear that the majority of the rogues that appear in a stock of Sweet Peas the second year, and what are known as recessive colour rogues, are to a great extent due to cross-fertilisation by some outside agency, and that this cross-fertilisation occurs in this country on a rather large scale, though not to so great an extent as it does in California. The agency most largely responsible for this cross-fertilisation in this country is considered by Major Hurst to be the leaf-cutter bee, which carves the semi-circular pieces out of the leaves of our Rose bushes, though weevils and blue tits were also considered to be possible agents.

It would seem, however, that the rogues due to various causes can be almost eliminated by breeding Sweet Peas on Mendelian lines as, when this is done, not more than five rogues per thousand are given, none of which are type rogues or recessive colour rogues, the five being all what are known as dominant colour rogues. In ordinary commercial stocks of Sweet Peas tested by Major Hurst, and which were not, of course, obtained by an application of Mendel's laws, one hundred and eight per thousand were rogues; while in the National Sweet Pea Society's trials conducted at Burbage, one hundred and fourteen per thousand rogues were found. In these instances many of the rogues were contrary to type, *i.e.*, instead of having the open keel that characterises the Spencer Sweet Peas, they had clamped or united keels. The complete removal of such type rogues would render the remaining stock perfectly true so far as type was concerned, and thus one evil would be eliminated. The dominant colour rogues, which always show the first year, could also be removed and thus got rid of; but the recessive

colour rogues, providing cross-fertilisation had been effected, would appear the following year. Constant vigilance is, therefore, necessary to reproduce any variety of Sweet Pea true year after year.

Naturally, a paper of this kind was of a highly technical character, but the importance of Major Hurst's revelations can scarcely be overestimated. Not only do Sweet Peas give us considerable joy in the garden and home; the growing of seeds in this country is now a large industry, providing employment for many thousands; and anything that will enable raisers to put stocks on the market that will not give more than five rogues per thousand will be of inestimable value. The whole of Major Hurst's paper, with the most salient points of the discussion, will be published in the National Sweet Pea Society's Annual, which will be worth buying for this feature alone.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Bracken on Victoria Embankment.—On the north side of the Victoria Embankment wall,

MR. E. BECKETT, V.M.H., HEAD-GARDENER
AT ALDENHAM HOUSE, ELSTREE.

(See page 541.)

facing Northumberland Avenue, may be seen some small specimens of Fern (*Pteris aquilina*) growing on the east side of the Bazelgette mural monument.—P. CLEMENTI-SMITH.

Tulipa primulina.—It is not quite fair that the primrose yellow form of *T. strangulata*, page 532, October 19 issue, should be called *T. primulina*, as there is a very distinct species described by Baker under that name. It is figured in t. 6786 of the *Botanical Magazine*. It is rather like an enlarged *T. biflora*, and has narrow leaves and slender stems, sometimes bearing more than one flower. It is much more suitable for the rock garden than any form of *T. strangulata*. It was discovered by Mr. Elves in the Aures Mountains in Eastern Algeria in 1882.—E. A. BOWLES.

Crab Apples as Ornamental Shrubs.—I was much interested in one of the leading notes on Crab Apple Veitch's Scarlet in the issue for October 12. I have had no experience of the variety named, but, judging from the description given in the note referred to, it is a beautiful one, and should have a prominent place in gardens. In Mr. Rolls' garden at Arcadia, Bournemouth, Crab Apples are made good use of in the borders, being grown among the shrubs, where their highly

coloured fruits show to great advantage. The variety John Downie has done remarkably well so grown. The trees are trained as slender pyramids, and they have been covered with fruits almost from base to top.—G. G.

New Market Chrysanthemums.—Among the smaller exhibits at the fortnightly meeting of the Royal Horticultural Society on the 8th inst. was that of market Chrysanthemums from Messrs. Cragg, Harrison and Cragg, Heston, Middlesex, yet because of their freshness and fine quality it was also one of the most attractive. There were several vases, each containing about a dozen flowers with nothing but their own good attributes to recommend them, though these were all-sufficient in the circumstances. The new single-flowered Celia (illustrated on page 539), of rich golden yellow, was particularly good and striking in colour and get-up, and well deserved its award of merit. H. W. Thorpe, a fine incurved white, was superb, its crisp petal denoting good keeping qualities. Cranford Yellow and Cranfordia (yellow) were very fine. Phœbe was excellent in mauve pink. The greatest colour novelty, however, was seen in Juliet, a decorative variety of dull reddish walnut tone, quite unique in its way.—E. H. J.

The Twelve Best Climbing Roses.—I think that possibly even a rosarian would accept a "dressing" from such an acknowledged authority as Mr. Herbert E. Molyneux. I asked for the opinion of others as to my selection of the twelve best climbing Roses, and therefore gratefully accept Mr. Molyneux's criticism. But I think I hardly deserved Mr. Molyneux's caustic remarks as to the failure of many of my selected twelve to comply with my conditions, for reference to my previous notes (*THE GARDEN*, September 21, 1912) will show that I was fully aware of that fact. I am much obliged to Mr. Molyneux for naming three climbers unknown to me, and I will certainly procure those which he so strongly recommends. I wish I could evince my friendly feeling by sending Mr. Molyneux a plant or two of Marie Bret; but as I have only three plants of that lovely Rose, and they were presents, I must content myself by merely stating that they were procured from P. Nabonnand. I must hurriedly conclude by reciting in its more correct form Mr. Molyneux's quotation, *De gustibus non est disputandum*, for I still prefer my list to his.—G. B. W.

Albino Forms of Geranium robertianum.—I am much obliged to your correspondents for their notes on white Herb Robert in response to my desire for information. Unfortunately, they have omitted to mention whether it was the red-stemmed or green-stemmed variety that they have found. I have frequently found colonies of the red-stemmed variety in wild conditions, but never the green-stemmed, and it was in order to ascertain whether the wild origin of this latter form was known that I showed the two forms at the meeting of the scientific committee of the Royal Horticultural Society. Similar forms exist of the white Ragged Robin (*Lychnis Flos-cuculi*). The red-stemmed one I found in the Norfolk Broads, after having kept an eye on the watch for it for many seasons when collecting Lepidoptera among the rosy masses of the type form. The green-stemmed was found in Cornwall, but is not nearly so strong a grower as the handsomer variety with red stems and calyx. In both plants, *Geranium* and *Lychnis*, the two forms breed truly from seed. The red-stemmed *Lychnis* gives a small percentage of pink flowers, but I have never known the *Geranium* to revert.—E. A. BOWLES.

Odontioda Charlesworthii.—During recent years many *Odontiodas* have appeared, but this is still one of the best in commerce. It was derived from the intercrossing of *Cochlioda noetzliana* and *Odontoglossum harryanum*, and is deep blood red in colour. In size, shape and general habit the *Odontiodas*, such as the one just noted and *O. Bradshawiae* (*O. crispum* × *C. noetzliana*), resemble *O. crispum*, and from a horticultural standpoint the scarlet *Odontoglossum* has arrived. This charming set will thrive if given the same treatment as Colombian *Odontoglossums*.—S.

New Zealand Shrubs.—I see *THE GARDEN* regularly, and am always keenly interested in the articles that appear therein. Especially of interest are any notes concerning Maoriland trees and flowers. I notice that a New Zealand shrub was awarded a prize at the big flower show recently. It is amusing to think that this shrub is one that is generally religiously weeded out where it appears in gardens here. Your paper described the flower as being crimson. Is it crimson or a very deep pink? I have seen the latter quite often, but never the former. The white *Manuka* is the most common. It grows all over the country here, particularly on poor lands. Standing on top of any rise, one can see it shimmering for miles. Sometimes the shrub grows to a considerable height, but the flowers are never plentiful when this is the case. In the public domain at Auckland there are preserved some fine specimens of old *Manuka* trees. — *MONA MACKAY, York Street, Parnell, Auckland, New Zealand.* [*Manuka* of New Zealand is correctly *Leptospermum scoparium*. It is regarded as a troublesome weed in some parts of New Zealand, but is, of course, very showy, and is grown here, more especially in gardens of the South-West, as an ornamental flowering evergreen. The new *Leptospermum Nicholii*, which won the cup for the best new plant at the recent International Show, is probably not the plant referred to by our correspondent, but a richer-coloured form of that or an allied species. Apparently some New Zealanders use the name of *Manuka* for all the species of *Leptospermum*, although some authors use it more particularly in connection with *L. scoparium*. The native name of *Kahi-Katoa* has also been applied to it.—Ed.]

November 2.—Brighton Chrysanthemum Show (two days).

THE ROSE GARDEN.

NOTES ON NEWER ROSES.

HYBRID TEAS.

(Continued from page 529.)

Claudius (B. R. Cant and Sons, 1910).—This is one of the Hybrid Teas that might have been found in the Hybrid Perpetual class, I should imagine, without any injustice being done. It is an excellent Rose, Hybrid Perpetual-like in growth and flower, colour deep rose self throughout of almost uniform character, of good shape, and the flowers are carried erect on good footstalks. It requires thinning, but is quite up to exhibition standard if this is done. Another good point in its favour is its scent, and I see it figures in the raisers' current

effect; the colour-scheme reminds one of the older *Dr. Campbell Hall*, but is, I think, even more pleasing. It has been awarded the gold medal of the National Rose Society, and, with good cultivation, produces a fine flower, but (why is there nearly always a "but"?) it is thinnish and must be cut just right. A good flower. It is one of the most beautiful of Roses.

Cynthia (William Paul and Sons, 1900).—A pale lemon yellow, nearly white, leaning largely to the Tea side of its parentage; of rather unusual shape, which can be described as globular rather than pointed, but none the less pleasing for that. We do not want all our Roses to be after one pattern. Good in autumn, with plenty of petals, and a fair grower.

Coronation (Hugh Dickson, 1912).—I have not yet received a copy of this firm's catalogue, so cannot be sure whether they are sending out this magnificent Rose this season or not, but I would rather not run the risk of leaving it out in case they may be distributing it this year. It is entitled to be called one of the best of the new Roses of 1912, and one can hardly speak too highly of it. I first saw it at the "National" at Regent's Park this year. There it won first prize in a very strong class of baskets for any white or pink, beating some very fine *Druschkis* in the process. The basket was removed to take its place as an exhibit in the class for new seedling Roses, and, as a consequence, upset some of the reports of the show. One gentleman of the Press, overlooking the fact that there might have been a first awarded, proceeded to lecture the judges for only awarding a second to a basket of *Fran Karl Druschki* that was the "finest he had ever seen, and should have been an easy first," &c. In that unaccountable way which cannot be easily explained, it did not catch the eye of the judges of the new seedlings at the "National" sufficiently to obtain an award. At Belfast, however, although I do not think it was a bit better exhibited, it obtained the gold medal, and undoubtedly deserved it. Most Roses have to come up twice before they secure a gold medal, unless they are particularly striking, such as Irish

THE NEW CHRYSANTHEMUM CELIA. A SINGLE VARIETY WITH RICH GOLDEN-YELLOW FLOWERS.

Fireflame, *Rayon D'Or*, or *George Dickson*, and *Coronation*, fine Rose that it is, was no exception. Afterwards, as seen growing at Belmont, it was manifest that no mistake had been made in this case. To adequately describe the flower is not easy. Here again we break away from the high-pointed centre, and *Coronation* is more of the type of *Mrs. Cornwallis-West*, or, to name a better-known but not a better Rose, *Her Majesty*. It is a delicate pale pink in colour, very large. I saw flowers as big as the closed fist of an ordinary mortal. No fault is to be found with its growth. The Rev. J. H. Pemberton was much enamoured with it at Belfast. Whether it goes out this season or not, all exhibitors should make a note of *Coronation* and be sure that they get it, as there is

catalogue at the moderate price of 1s.; so those exhibitors who have not grown it should give it a trial.

Comtesse Icy Hardegg (Souper et Notting, 1908).—A very bright carmine of good shape and growth that, if freely disbudded, will give quite a good flower. It has done very well with me during the past season; it has plenty of petals and it stands well when cut. The colour does not seem to fade so rapidly as is the case with most carmine varieties. A Rose that has been somewhat overlooked.

Countess of Shaftesbury (Hugh Dickson, 1911).—This is a very beautiful colour, not easy to describe—silvery carmine, with a lighter shade at the edge of the petals that heightens the general

effect; the colour-scheme reminds one of the older *Dr. Campbell Hall*, but is, I think, even more pleasing. It has been awarded the gold medal of the National Rose Society, and, with good cultivation, produces a fine flower, but (why is there nearly always a "but"?) it is thinnish and must be cut just right. A good flower. It is one of the most beautiful of Roses.

another Coronation on the market—a pretty wickham of Turner of Slough—that may lead to confusion.

Duchess of Normandy (P. Le Cornu, 1912).—A yellow sport from Dean Hole, exhibited by the raiser at Southampton this year, where it received a card of commendation and might, perhaps, have had a higher award. I was very pleased with it, and I think, due allowance having been made for the Jersey soil, and, further, the Jersey climate, with its almost perpetual sun, preventing that slow development of the bud which is so essential to produce the exhibition flower, it is a really promising sport that should do well in our English gardens. A yellow Dean Hole hardly does justice to its colouring. It is not, at any rate, a yellow self, but has many shades of colour among its petals, salmon and gold predominating. Altogether a beautiful Rose that I expect to see in most exhibition boxes before we are much older. It is being distributed at 5s. each. Duchess of Normandy, by the way, is the Jersey man's title for Queen Mary.

Southampton. H. E. MOLYNEUX.

FLOWER GARDEN.

SWEET PEA NOTES.

A Moseley List.—During the last decade many old-established firms which had not previously devoted special attention to the cult of the Sweet Pea have come within the fold, either because their principals became enamoured of the Queen of Annuals or because it was thought that a little grist might be added to the mill. Why Hallams, Moseley, threw themselves so keenly into the Sweet Pea business I should not like to say definitely, but I do know that Mr. Arthur Hallam is one of the most enthusiastic men in the trade, and that there are few things in connection with it which he does not know, provided that they are worth knowing. This Moseley list is a modest one, and it does not comprise any of the firm's own novelties; but, as far as possible, all the finest varieties raised by others are listed, from Afterglow in the "A's" to Winsome in the "W's."

Edinburgh Sweet Peas.—There are doubtless several seed-houses in Edinburgh selling excellent Sweet Peas, but I dare venture to assert that the brain of every reader of THE GARDEN will picture the name of Dobbie when the heading of this paragraph is seen. In the old days it was Dobbie of Rothesay, but most of us have forgotten that the firm was ever located in that charming spot. The Edinburgh seed is grown in Essex, and the crop this season is a remarkable one, as well for excellence of quality as for abundance. No fewer than nine novelties are listed, and of these two have received

the award of merit of the National Sweet Pea Society, two others have secured the award of merit of the Royal Horticultural Society, while still one more was honoured at the Royal International Horticultural Exhibition—a record for one season of which any firm might well feel proud. There is, however, just one point more to add. Lady Miller is one of the two varieties reserved for the silver medal of the National Sweet Pea Society, provided that they behave themselves properly next season. It is an exquisite Sweet Pea that grows splendidly and produces plenty of fours. The colour is delicate apricot rose on

distinguished approbation of the King. It is the same colour as Lady Grisel Hamilton, but of Spencer form. Brunette is reddish mahogany; at least that is the nearest I can get to the colour. It is distinct and decidedly handsome, even if it has not quite the size of some of the modern giants. Old rose is the colour of Decorator, and it is well named, for it is admirable for the purpose indicated. It will be offered by more firms than one, but the name has met with general acceptance. Lavender George Herbert is Dobbie's special stock of a grand Sweet Pea. Mark's Tey is a weird mixture of maroon, rose, mauve and blue which does not appeal to my particular taste; but this does not alter the fact that it is a fine bold flower of splendid form, produced by a plant which grows vigorously. Inspector is a duplex form of Earl Spencer, and must not, therefore, be exhibited at any show next summer where double standards are strictly taboo. In addition to these the firm offers all the finest Sweet Peas in general cultivation.

A Waterlooville Letter.—Mr. W. E. Alsen, Denmead, Hants, has not yet sent me a copy of his catalogue, but informs me that he will offer Annabel Lee, a distinct lilac which was shown at the "International"; A. A. Fabius, a superb cerise which has been seen before, but has not been satisfactory on account of lack of fixity; and Minnie Furnell, the shrimp pink which is such a warm favourite with the ladies.

HORACE J. WRIGHT.

AN ORNAMENTAL SYCAMORE.

(ACER PSEUDO-PLATANUS ERYTHROCARPUM.)

THE beauty of several Acers, Maples or Sycamores when laden with highly-coloured fruits has been very noticeable in Southern Counties during the present year. The hot summer and autumn of 1911 are no doubt responsible for the freedom with which the Acers have flowered and fruited this year. One of the best of these red-fruited kinds is that named above, which is a form of the common Sycamore. It is also sometimes known as A. van Volxemii variety erythrocarpum. Every branch of the tree was as heavily laden with fruits as the small spray illustrated. Some of

A FRUITING SPRAY OF ONE OF THE SYCAMORES. THE WINGED FRUITS ARE CRIMSON IN COLOUR.

cream. Dobbie's Scarlet is distinct and excellent; indeed, it is a colour by itself, and one which every grower will desire to have in his collection. The flowers do not burn. This firm's strain of Thomas Stevenson was the reserve for this year's medal, but it failed to realise expectations by throwing a rogue. It was hard luck, but does not alter the fact that the colour and form are alike superb, though, in my opinion, no better than those of other strains of the same variety that I have seen on occasions. True Lavender met with the

long, drooping racemes measured a foot in length, carrying thirty to forty pairs of red fruits. Quite a lengthy list could be given of Acers with ornamental fruits. Three others especially worthy of note are the Pilgrim Plane (a form of the Sycamore), the Caucasian A. Trautvetteri and A. insigne (velutinum). These highly coloured and unique looking fruits make a most interesting feature in the woodland during the early autumn months, and for these alone the trees named above are well worth growing.

A VIEW IN THE ROCK GARDEN AT FRIAR PARK, HENLEY-ON-THAMES.

COLOURED PLATE.

PLATE 1457

ROCK GARDENS IN THE MAKING.

THE Editor has commissioned me to write a series of articles on a subject at once fascinating, popular and seasonable, and in such a manner as to afford the general reader some idea of how to get to work and the possible, or very highly probable, results of his labours. Just what the results prove to be will be very much a question of space, of the desires of the individual operator, and not a little, naturally, upon ways and means.

Be the space never so circumscribed, however, or ways and means ever so limited, there should exist in the mind's eye, at least at the start, some sort of ideal—some finality—to which it is desired to attain. Whether this is so in the case of Sir Frank Crisp—the greatest apostle of rock gardening this, or probably any other country, has ever known: his creations at Friar Park have been described as the noblest example of rock gardening outside the Alps themselves—I do not know, since on making enquiries as to where the end was likely to be, the eye was directed to a certain boundary limit where it was intended to stop "for the present." To reach even that provisional boundary, however, the operators have yet to cover an acre or more of ground to bring into position and to render available and congenial for alpine vegetation a few more thousand tons of rock, so welding them together and furnishing them as to constitute one great imposing flank of a still greater, more imposing whole.

Obviously, then, all our rock gardens cannot be of this kind, though they may, one and all, if rightly constructed and fittingly planted, afford pleasure by their presence, while adding variety and charm to our gardens. Those whose privilege it has been to see the wonderful rock garden at Friar Park in the heyday of its summer glory will not require to be told of its beauty, its naturalness, or the wealth of picture-making subjects it contains. Those who have not will be able to get a glimpse of a small portion of it from the coloured plate which is published with this issue. For the rest—the acres of it and the thousands of tons of rock—the reader must for the moment rely on the imagination. To all, however, should be very clear the style of arrangement and the method of furnishing, while the wedding of rock with alpine and alpine with rock is so strong a feature of the picture that it is not likely to be overlooked by those interested in such matters. To render the matter more generally helpful, however, I hope to direct attention to, and drive home if possible, some of the object-lessons this famous garden teaches, since the principles adopted—the essentials in the case—are applicable to all rock gardens, small and large alike.

The Object of the Rock Garden.—Primarily it should exist for the betterment, both as regards display work and cultivation, of that great mass of mountain plant-life we know as "alpine,"

If it fails in these, it fails also in its mission, and might as well be non-existent. In some degree it has, of course, to be admitted that rocks are not essential to the cultivation of many alpine plants, the more vigorous of them, and those of the upland pastures in particular, not infrequently constituting the verdure at one's feet and unassociated with rock. At higher elevations rock and alpine are more general, and, higher still, the one would appear inseparable from the other. It is to these latter that rocks are more or less essential, and to which the richer soils of the garden are not infrequently unsuited because of the greater amount of humus they contain and their imperfect drainage. To such as these, then, the rocks become a sort of necessity. In other directions they are as a means to an end, and favour the bringing together into nutshell form a varied class of vegetable-life having much in common from the cultural standpoint. Quite

good effect. Not only are the plants disposed in a manner consistent with that obtaining in their native haunts, but they are also raised nearer to the line of vision, while separated from those greater dangers of soil, damp and insect-life which continually threaten and not infrequently overwhelm them when grown in the so-called "choice border," whatever that might be. These, then, are some among the more fundamental reasons for the presence of a rock garden on which to grow alpine plants.

E. H. JENKINS.

*(To be continued.)***GARDENS OF TO-DAY.****AUTUMN EFFECTS AT ALDENHAM HOUSE, ELSTREE.**

THE beautiful gardens and pleasure grounds at Aldenham House, Elstree, the country seat

BRIDGE OVER ORNAMENTAL WATER IN THE GARDENS AT ALDENHAM HOUSE.

naturally, this can only be done in a modified degree, since, after all, the rocks play but one part in the cultivation of the plant, although an important one. Away from their native haunts they are bereft of the pure, rarefied air of the mountain, the great elevation and, not least, that Nature-given mantle of snow which is one thing to them in winter and another in summer—a blanket to wrap them while asleep, and a generous supplier of moisture to them in their waking hours.

Notwithstanding these shortcomings, however, the vast majority of alpine plants are amenable to cultivation in British gardens on intelligent lines. It may be on elaborate ones such as those indicated by the coloured plate, or a miniature of them, where similar principles exist as the outcome of thoughtful and careful work from the start.

Then, again, among the foremost reasons which might be given for the presence of rocks is the fact that in no other way can these miniatures of mountain vegetable-life be displayed to such

of the Hon. Vicary Gibbs, are famous throughout the world, principally on account of the rich and varied collection of hardy trees and shrubs that is to be found there, and with which no one is more conversant than the enthusiastic owner, who is always glad to impart his wonderful knowledge to any enquirer. He is widely known as a great exponent of the art of pruning and planting especially, and also of the value of trees and shrubs for beautifying the landscape. The magnificent vegetables that are so well grown and exhibited by the well-known head-gardener, Mr. E. Beckett, V.M.H., whose portrait will be found on page 538, have also made these gardens famous. But in the space at our disposal it is impossible to adequately describe gardens and grounds of such spacious dimensions, and we will therefore confine ourselves to a few of the more important features that we noted when visiting the gardens during the early days of October.

The Michaelmas Daisies.—Although Mr. Beckett has been working for the improvement of these useful hardy flowers for many years, it is only during the last decade that the results of his labours have been brought before the public, and even now we doubt whether the average grower of herbaceous plants realises what a wealth of late autumn beauty is to be found in these much-maligned flowers. At Aldenham, Mr. Beckett has a large border devoted entirely to these, and the illustration on page 543, taken about mid-October, will give at least some idea of their gracefulness and charm, though it entirely fails to depict the many colour gradations and variable outlines that may be found among them.

This border is nearly one hundred yards long, and from 20 feet to 30 feet wide. It is filled mostly with forms of *Novi-Belgi* and *Novæ-Angliæ* for the background, with the small-flowered *ericoides* and *cordifolius* sections in the foreground. In common with most good cultivators of hardy flowers, Mr. Beckett is a firm believer in frequent division of the old plants, and his Michaelmas Daisies are lifted every year during January or February, the soil well and deeply dug and manured, the plants divided, and only the strongest portions replanted. It may be useful to give the names of a few of the best varieties that are to be found at Aldenham, and most of which can now be obtained from many plant nurseries. Among the large-flowered sorts, *Climax* stands out supreme. It is a tall-growing variety, attaining a height of 6 feet or more, and is later in blooming than some. But its blossoms are large and deep sky blue in colour, and may aptly be described as blue *Marguerites*. Mr. Beckett has a beautiful white-flowered seedling from *Climax*, but this is not yet in commerce. It is a gem among hardy plants, and is named *Avalanche*. *Amethyst* is a new one, with rather paler-coloured flowers, the petals of which are long and narrow and slightly twisted, this giving them a very charming appearance. *Attraction* is another large, blue-flowered variety of considerable value for cutting. A variety that particularly pleased us is *St. Egwin*. It has a compact, bushy habit, but the flowers are a delicate shade of rose pink, and it makes a superb feature in the border. *Sirius* is a delightful, tall, erect variety, with semi-double flowers of deep rose colour; for cutting it is ideal. Among the dwarf, early, *Amellus* section, Mr. Beckett has many good varieties, notably *Comet*, with large, deep blue flowers; and *Trumpeter*, with paler blossoms. In the small-flowered *ericoides* and *cordifolius* sections there are so many good sorts that it is difficult to make a selection. The following are, however, all excellent: *Simplicity* (pale lavender), *Perfection* (white), *Daydream* (white), *Little Boy Blue*, *Hon. Viary Gibbs* (old rose colour), *Captivation* (pale rose), *Ideal* (pale blue), *Paragon* (pale blue), *Desire* (white—see illustration), and *Hon. Edith Gibbs* (a well

known and invaluable variety, pale blue in colour). *Cordifolius elegans*—Mrs. Rayner (invaluable for colour), *Little Bo-Peep* (new blue), *Enchantress* (a fine variety), *Freedom* (small white), *White Heather* (new), and *Esther* (dwarf pink).

Ornamental Trees and Shrubs.—In what is known as the wilderness at Aldenham a feature is made of grouping a number of trees and shrubs for summer, autumn and even winter effect, and this might in many open woodland spaces be adopted with equal success. Very large beds, well in keeping with the hounteous proportions of the estate, are planted, each with one kind of shrub, and it may be useful to mention a few of the kinds that

relied upon for next year's display. Then there was *Rosa rubrifolia* trailing over old tree stumps. Its purple hue had departed, giving place to scarlet fruits and yellow colour tones in the foliage. By the side of the large lake, *Cornus alba*, with its crimson foliage, soon to depart and reveal the brilliant red stems that make this Dogwood so valuable for winter effect, was massed with a lavish hand; so also was its variegated-leaved form, which added a touch of silvery sheen to land and water. *Spiræa prunifolia*, with crimson foliage, and red and yellow stemmed Willows all find a home beside the lake, and play their part in a well-thought-out scheme of colour effect for at least three seasons of the year.

Some Autumn Beds.—Though late in the season for bedding effects, there were still some brilliant flowers to be seen. The Fuchsias in particular were excellent, a bed filled with the hybrid *Coralie*, with its large clusters of semi-pendulous, coral red flowers, being particularly pleasing. Then there was the variety *Brilliant*, large plants of it freely bedecked with flowers, with a groundwork of golden-leaved *Alternanthera* and edged with *Echeveria*.

Autumn Roses.—The Rose garden at Aldenham is laid out in formal style, with turf paths between the beds, each of which accommodates one variety. The whole is enclosed in a Yew hedge, so trained and clipped as to form a living wall, with tiered pillars at the corners. This not only makes the Rose garden a secluded place, but protects the Roses from keen, biting winds, which do so much damage in early spring. *General Schablikine*, a Rose that ought to be grown much more than it is, was abundantly clothed with its coppery red blooms. *Coralina*, *Grüss an Teplitz*, *Gustave Regis* and *Papa Gontier* were others that called for special mention as suitable Roses for late flowering.

Rare Trees and Shrubs.—As we stated at the outset, the gardens at Aldenham are rich in rare trees and shrubs, but lack of space forbids detailed mention of these now. We hope, however, at some future time to refer to them more fully, and also to the wonderful *Streptocarpus* that Mr. Beckett has raised during recent years. So extensive are the gardens and pleasure grounds, and so well stocked are they with good and interesting things, that one

would need a whole issue of *THE GARDEN* to merely touch on each section. In spite of natural difficulties in the way of heavy clay soil, Mr. Beckett grows everything well, and the gardener, whether he be amateur or professional, who is privileged to visit the gardens at Aldenham House will find many object-lessons that may well be taken to heart.

By the kind forethought of the Hon. Vicary Gibbs, these gardens are thrown open to the public each Saturday afternoon during August, and, judging by the numerous visitors, this is much appreciated. Genuine lovers of gardens may at almost any time view the gardens by appointment.

ASTER DESIRE, A CHARMING MICHAELMAS DAISY RAISED AT ALDENHAM HOUSE.

were particularly interesting at the time of our visit. *Aronia floribunda*, now referred to by the Kew authorities as *Pyrus nigra*, was resplendent in its brilliant scarlet-crimson foliage, and in places where this had departed one could see the green-coloured stems that would take up their place in the colour effect for winter. *Spiræa Douglasi*, planted very thickly so as to form a mass, was still retaining its pink flower-heads, though most of the colour had departed, while the leaves were a beautiful golden yellow, and would be succeeded later on by the soft brown stems. Early next spring these will be cut down close to the ground, and the young growths that spring from the base

THE FRUIT GARDEN.

THE BEST PEARS AND THEIR CULTIVATION.

THE question of growing Pears is one that should always be approached with some humility. The fickle nature of this fruit, so easy to cultivate in some respects and so difficult in others, makes it a pleasurable problem. It is somewhat of a conquest to bring to the fruit-room a collection which will carry the Pear season on to April or May, but it demands something of genius to send them all to table in the best condition. To many this difficulty makes their cultivation more interesting, and for the others there are sorts which will do remarkably well with less careful study.

The Best Soil.—The general remarks in a previous article, page 479, issue September 21,

pyramid and bush forms, and where decorative trees are not required, no form is better than these or the slight modifications known as the vase or goblet trained—terms which explain themselves. The tendency to overproduction of spurs must be kept in check, or a dense mass of foliage alone will result.

Why Pears Fail.—The reasons why Pears fail in many districts and in some hands are many, but among these I may mention the following: When bloom is plentiful and fruits few, the Pear midge may be suspected. Examine young fruits and, if they contain some small, white maggots, gather and burn all affected fruits and dress the ground with kaintit. Or it may be that, if only one variety is grown, it is self-sterile and requires pollen from another to fertilise it. The remedy is obvious. Cracked fruit is caused by the black scab (*Fusicladium dendriticum*),

left on the tree as long as they hang firmly; but the earlier sorts must not be allowed to turn yellow, and should be gathered even when they part unwillingly from the tree. The failure of late Pears to ripen is nearly always due to either lack of sun or water or to early gathering. It is a frequent mistake to place late Pears on a north or east wall and the early ones in more sunny positions. Reverse the positions, water the later sorts freely, thin out the foliage round the fruit, and you will be repaid.

The Best Varieties.—The varieties to choose from approach in number the sand of many seas. A German book is on my table describing 1,040 varieties. Most of us will, however, be content with fewer than this number! To start the season the old Jargonelle has stood the test of three centuries, and still remains one of the best. Doyenné d'Été, though small, is a free bearer

A BEAUTIFUL AUTUMN BORDER. MICHAELMAS DAISIES GROUPED FOR EFFECT AT ALDENHAM HOUSE, ELSTREE.

as to planting fruit trees need not be repeated here, and it is only necessary to qualify these in so far as soil is concerned. The ideal soil is a deep loam or brick earth on a subsoil which retains a supply of water. The Pear is perhaps more often starved from lack of water than want of food. The use of the Quince stock, however, makes it possible to grow the trees on shallow soils, and is thus of the greatest importance for this purpose, also for inducing earlier bearing, so that we now may plant Pears without a single wish to benefit posterity.

Pruning.—In the matter of pruning, no tree is more long-suffering. It will stand up to the most desperate pruner and give him a chance to repair his errors. It submits to the restriction of training very readily, and as horizontal, fan-shaped and double cordons is most valuable. Its natural conical habit renders it *facile princeps* for the

and unhealthy roots and unkindly subsoils are a contributing cause. Gather and burn affected fruits, and prune out all wood which shows the ruptured bark so characteristic of this disease. Lack of flavour may be due to want of proper pruning. Pears refuse to develop their best fruits under a dark mass of leaves. Let in the light and air. Again, it may be that persistent nitrogenous manuring causes rank growth, and in this case stop the offending cause and apply basic slag in the autumn and a lighter dressing of superphosphate in the spring.

When to Gather Pears.—A most frequent complaint is of fruits rotting at the core. This is also caused by too much nitrogenous manure (or overdoses of water) and gathering too early. All early Pears must be gathered before they are ripe, a fact that cannot be too often repeated or with too much emphasis. Late Pears must be

and quite good for its season. In September comes the favourite Williams', needing no recommendation and merely a caution that its flavour must not always be judged from fruit sold under this name. Souvenir du Congrès follows, and is of first-class quality, with melting flesh. Marguerite Marillat comes between the last two named, but is rather more for the show than for the dinner table. October and November bring in so many fine sorts that selection becomes more than usually difficult.

Considering cropping powers first, we must admit Conference and Durondeau, both of which are good, and the former an example to all Pears in the matter of regularity of fruiting and freedom from disease. Beurré Hardy also fulfils the promise of its name, and adds to this quality good appearance and flavour. To these we must add Marie Louise, Louise Bonne of Jersey and Emile d'Heyst,

old and well-tried favourites. On the *bonne bouche* principle I now cite the Queen of Pears (the feminine gender always seem appropriate in this connection), Doyenné du Comice. To paint the Lily or add flavour to the Comice are tasks of equal undesirability.

The Christmas dessert will be supplied by Winter Nelis (for those in warm climates), and the new Santa Claus is a visitor who bids fair to be as welcome and as universal as his namesake. Of the after-Christmas Pears, Olivier de Serres, named after the great French agriculturist, is, despite an unpromising exterior, most excellent in flavour and a fertile variety, and Josephine de Malines will carry the Pear season into March. If another variety is wanted, the claims of Duchesse de Bordeaux should be carefully considered. A word as to cooking Pears. In my opinion none equals *Bellissime d'Hiver*. It lasts long in season, often till April, and its freedom from grittiness is not the least of its virtues.

EDWARD A. BUNYARD.

THE GREENHOUSE.

BEAUTIFUL WINTER GREENHOUSE FLOWERS.

(BOUVARDIAS.)

THE different Bouvardias form a delightful race of flowering plants for the greenhouse, among their prominent features being the fact that they are at their best during the autumn and early winter months, and that they possess a certain air of refinement and are, consequently, worthy of association with any other flowering subjects, however choice. In my young days a cluster of Bouvardia was considered to be an ideal button-hole flower; now, however, the flowers are not large enough to satisfy the votaries of fashion, but there are still some who decline to follow the beaten track, and prefer a small or medium-sized flower.

Apart, however, from any consideration as a cut flower, neat, bushy plants of the different Bouvardias are exceedingly valuable for the embellishment of the greenhouse, where they retain their beauty for a considerable time. Their culture is not at all exacting, as a few old plants put into a gentle heat early in the year will push out a quantity of young shoots, and these, when from $\frac{1}{2}$ inches to 2 inches long, form the best of cuttings. In fine, sandy soil they will quickly root in a close propagating-case, when they must be potted off and shifted into larger pots when necessary. They should be occasionally stopped in order to induce bushy plants, while a liberal proportion of leaf-mould in the potting compost is all in their favour. Pots 5 inches in diameter are large enough to accommodate plants struck from cuttings in the spring, but, of course, older ones may be grown in pots much larger than that. For many decorative purposes, however, 5-inch pots are quite large enough.

At one time Bouvardias were often planted out during the summer months, and lifted and potted before flowering. This practice is not so much carried out as it formerly was, prominent objections to it being the fact that it was necessary to employ somewhat large pots, otherwise the leaves were liable to suffer. Besides the young shoots, Bouvardias can be propagated by root-cuttings, and they were at one time extensively treated in this way, but it is not now much employed. A curious feature is that plants from root-cuttings are, if the variety has been obtained from a sport, occasionally liable to revert to the typical kind. This was first brought home to me in a very unpleasant manner, for when the double white variety Alfred Neuner was sent here from the United States, just over thirty years ago, I, being anxious to obtain as large a stock in as short a time as

Cleveland, the best of its colour, a vivid scarlet; Priory Beauty, deep pink; and Pride of Brooklyn, a better white than *Vreelandii*. The large, pure white, deliciously-scented *B. Humboldtii corymbiflora*, which may be had in flower in the summer, must on no account be passed over in any selection of the very best kinds.

H. P.

CATALOGUE ILLUSTRATIONS OF BULBS IN POTS.

THE custom of issuing well-got-up catalogues with illustrations of many of the bulbs therein offered for sale is becoming more general. Very many nowadays contain pictures of the whole plants as they are grown either in pots or bowls. It is of these I feel constrained to make a few remarks. Some must surely be put in as awful examples of how "not to do it." Can anything be more spoiling to the natural beauty and gracefulness of the Daffodil than some of those overloaded and over-flowered potfuls, which may be wonderful examples of culture and well-prepared bulbs, but which also indicate that this or that particular gardener's skill has, alas! got the better of his taste.

I have picked out the illustration shown as being one of the best-got-up of its kind that it has been my lot to come across. If each compiler of catalogues and every reader of *THE GARDEN* will only copy the spirit of this bowl of *Campernelle Jonquils* when they are potting their bulbs, I am sure they will be very pleased with the results next spring; hence my first bit of advice, "Don't overcrowd."

Another point of considerable importance is the height of the receptacle in which to grow the plants. It has been abundantly demonstrated that for decorative purposes nearly all bulbs will do as well in shallow pots as in the old-fashioned deeper ones. To my mind there can be no question which is the more pleasing, and as I have said more than once in *THE GARDEN* pages, I have taken almost entirely to the former. So my second wrinkle is, "Use shallow bowls or pots."

Again I would ask readers, if they have not already done so, to notice the difference in the look of perfectly plain bowls and those with

A BOWL OF CAMPERNELLE JONQUILS WELL ARRANGED FOR EFFECT.

possible, struck a number from root-cuttings. When these flowered many of them reverted to the single *Davisonii*, from which Alfred Neuner originated as a sport, whereas all those struck from the young shoots retained their double character. Some of the best varieties include: With double flowers—Bridesmaid, bright pink; Hogarth *flore pleno*, rosy scarlet; President Garfield, soft pink; Victor Lemoine, scarlet; and the white Alfred Neuner, above alluded to. With single flowers—Dazzler, scarlet; Hogarth, soft scarlet; *jasminiflora alba odorata*, white, with a reddish tinge at the backs of the petals, deliciously scented; *jasminiflora paniculata*, pure white; King of Scarlets, a large flower, scarlet, with white tube; Mrs. Robert Green, soft salmon pink; President

some ornamentation either in colour or in an embossed pattern. Speaking generally, I feel there can be no comparison between the two. The plain are so much nicer and set off their contents so much better. After a good deal of consideration and observation I have decided in my own mind that the best colour of all is a dull brown, not only for bowls, but even for pots. What is known as Silchester ware is the sort of thing I mean. I am having some made for me this year, and, as I am daily expecting them, I shall be able to grow a more varied collection than I have hitherto done. In the spring I hope to report. Thus the third and last point that I would urge on "potters" is, "Use as plain and unornamented bowls or pots as possible, and try those coloured brown." JOSEPH JACOB.

GARDENING FOR BEGINNERS.

SIMPLE BEDS OF BULBS AND OTHER SPRING FLOWERS.

THERE are many kinds of spring-flowering plants that may be associated with bulbs, the beauty of the flowers of the latter being much enhanced by the close proximity of the other kinds of flowers. The spikes of the bulbs, especially those of Hyacinths, Tulips and Narcissi, grow a fair height above the soil. The growth of many kinds of hardy spring flowers is, in comparison, dwarf, so that the latter may be used as a groundwork to the taller flowers or as a bordering to the various beds. The beds shown in both A and B designs are suitable for planting as separate borders in any garden, on a small or large scale, and, of course, the whole design in each case may be used on a lawn or cut out, edged with tiles and gravelled between.

Effective Ways of Planting the Beds.—The long central bed may be filled as follows: Nos. 1 1 1, Hyacinth La Grandesse; Nos. 2 2 2, Hyacinth Roi des Belges (dark red); No. 3, entirely filled with *Aubrietia deltoides* (lavender blue). The whole bed would thus show the colours red, white and blue. No other bordering would be needed, as the *Aubrietia* would form it in the way of a carpet bordering. Where the three sets of beds are planted close together, as drawn, the two outer ones may be filled as follows: Nos. 4 4, Tulip Keizerskroon, scarlet, with yellow border; double white *Arabis* as a groundwork. Nos. 5 5, Tulip Queen of the Netherlands, blush colour; *Aubrietia Leichtlinii*. Nos. 6 6, Tulip Duchess de Parma, orange red, yellow border; groundwork of white *Arabis*. All other divisions, Nos. 7 7 7 7, filled with Hyacinths King of the Blues and L'Innocence, blue and white respectively, and single-flowered *Arabis alpina* as an edging only, but not as a groundwork for all the Hyacinths. No. 1 design, B, may be filled with Hyacinth *gigantea*, or *Norma* or *Moreno*, all pink-flowered, and *La Grandesse*, white, with a groundwork of *Forget-me-not*, or an edging, No. 2, of the latter plant. Nos. 3 3 and

EFFECTIVE WAYS OF PLANTING SPRING FLOWERS.

Nos. 4 4, Tulip *Dusart*, dark red, and *Arabis alpina*, respectively; Nos. 5 5 and Nos. 6 6, Hyacinth *Grand Maitre*, light blue, and single-flowered *Arabis*, respectively; Nos. 7 7, Tulip *Mon Tresor*, yellow; Nos. 8 8, *Aubrietia Crimson King*, dark red; Nos. 9 9, Tulip *Rose Gris de Lin*, a pale rose; and Nos. 10 10, *Silene pendula compacta* or *Silene acaulis*, both pink-flowered.

The Soil and the Planting.—As it is not desirable that the groundwork plants should be very gross in growth, manures must not be applied to the soil in such a way that their roots will come in direct

contact with it long before the flower-buds are formed. The necessary rotted manure must be dug in very early before the bulbs are planted. The surface or groundwork plants must be put in first. Where bulbs are associated with other kinds of plants, it is well to allow them more space than in cases where they alone occupy the beds. The surface plants must be put in far enough apart to allow of due expansion of growth without overcrowding. These should, when in full bloom, form a dense carpet or a compact edging, as the case may be. G. G.

SEDUMS FOR THE ROCK GARDEN.

SEDUMS are most useful plants for the rock garden, and there are many beautiful species and varieties. The various tints of foliage make them most interesting plants to study during the winter, and when in flower during early autumn there are no plants which give a more charming effect. I will name a few of the best in the mossy section, which may be grown in the rock garden as wall plants, or any place where the roots can obtain a foothold: *Minima*, the flowers of which, greyish white, are produced so freely that they nearly hide from view the tiny glaucous foliage; *glaucum*, flowers white, glaucous foliage; *hispanicum*, pinkish flowers; *Lyidium*, pink; *spathulifolium*, yellow flowers, the foliage very pretty, of fleshy habit, but compact and close-growing; *anopetalum* I am including among the mossy section on account of its close-growing habit—the flowers are a beautiful pale pink; *boloniense*, yellow; *virens*, yellow; *album*, white, very pretty; *turgidum*, creamy white, a neat-growing variety; *Willisii*, white, star-like flowers; *maweanum*, yellow; *grandiflorum*, a very pretty yellow variety; and *sexangulare*, a neat-growing yellow kind. These are about the best of the mossy section. J. L. E.

SIMPLE DESIGNS FOR SPRING BEDS AND BORDERS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Autumn-sown Sweet Peas.—The sowing of these in pots to be wintered in a cold frame for planting out early in the New Year should now be done. The practice is very similar to that of spring sowing, but by this method considerably earlier supplies of flowers will be obtained. Select, if possible, a shallow frame and one with a firm bottom of ashes. When the seedlings are up, remove the light on every favourable opportunity, taking care to protect the plants from sparrows.

Shrubs for Bedding.—Where the use of other material for enlivening the beds during winter and spring cannot be used, such as perhaps low, shady positions, an excellent effect can be had by planting small shrubs in variety, both evergreen and a few deciduous, and these are at once attractive and continue so the whole time. For this purpose there are many subjects that can be utilised, and a few should be propagated or secured each year, so that the larger ones may be worked out on to the shrubberies. A few of the things that may be used are various Hollies, Cupressus, Osmanthus, Phillyreas, Andromedas, Aucubas, Box, Ericas, Euonymus, Pernettyas, Skimmias, Veronicas, Laurustinus and Vincas.

The Rock Garden.

Fallen Leaves.—Not only for the general appearance, but also for the benefit of the plants, it is important that the plants and rockery be kept clear of fallen leaves, otherwise when these commence to decay much damage may arise to the more tender subjects. Continue to remove any exhausted growth, and make the appearance of the whole as pleasing as possible. It is at this season when our lesser shrubs and foliaged plants are appreciated.

Protection.—Possibly many plants are not sufficiently hardy to stand several degrees of frost, and therefore temporary protection must be afforded them. This is much preferable to covering the plants entirely, excluding all light for two or three months. One of the best means and the neatest is the use of small pieces of Spruce boughs, which can be pointed and put in on the coldest side of the subjects. Others less hardy may be completely enveloped with them. For low-growing, dwarf plants we use small cages of coarse wire-netting and pack them with a little dry Bracken, while a covering of cinder-ashes over the roots will be found an excellent protection both from cold, damp and slugs.

Plants Under Glass.

Carnations.—The Tree Carnations should by now be commencing to flower freely. The plants will need occasional tying and the yellow leaves removed. Give the surface soil a pricking over and sprinkle a little artificial plant food specially recommended for them. The plants, to continue healthy and throw strong shoots, must have free ventilation, accompanied by just a little heat, and a night temperature as near 50° as possible will be found about right. Water as often as required, and assist the plants with applications of weak liquid manure.

Primula kewensis.—This plant will be better if housed, as it is liable to injury from frost unless well protected in the frames. Water carefully and assist the plants by the use of a little stimulant. For winter and early spring flowering it is an excellent subject.

Gladioli.—For greenhouse decoration in the spring the Gladioli are indispensable, and a supply of suitable varieties may now be potted up into 5-inch and 6-inch pots. Use a light and rich compost, place the corms just under the surface fairly close together, and treat as advised for Freesias. For this treatment The Bride (pure white) and Blushing Bride will be found admirable.

Chrysanthemums.—The large blooms this year are not quite as satisfactory as usual, owing to the inclement weather experienced during the summer, and many are very late. Endeavour to make the display, however, as attractive as possible by grouping the plants together. Give sufficient water when in flower to prevent excessive dryness, and air freely during the warmest part of the day.

The Kitchen Garden.

Asparagus.—The growth on the beds will now be sufficiently ripe for cutting down, removing it to a vacant piece of the garden and burning it. During frosty weather cover the beds with a little decayed farmyard manure, first removing all weed growth.

Winter Greens.—Keep the ground clean among these plants, and remove any bottom foliage that shows signs of decay. Make the plants well firm, and do the best to get them hardy before severe weather sets in by a free circulation of air and sun.

Cabbage.—Plant another batch towards the end of this month, and draw a little soil up to the earlier plantings as a protection. Plant just as thick again as the plants are to remain.

Fruits Under Glass.

The Orchard-House.—The majority of the pot trees of Apples, Pears, Cherries and Plums ought by this date to be completed with regard to potting or top-dressing, whichever is necessary. The staple portion of the soil should be the best fibrous loam, to which add some lime rubble and oyster-shell (particularly for stone fruits), a little soot, wood-ashes and crushed bones. Pot firmly, not too deeply, and well water in. If top-dressing only is necessary, see that the drainage is perfect before adding new soil.

The Water Garden.

Autumn Effects.—The value of the various water-side plants is now apparent, and any alterations to be made when growth is removed should now be noted. The Typhas, especially the small one, *T. angustifolia*, is very attractive, as is also *Phragmites communis*, *Cyperus longus*, *Glyceria spectabilis* the giant Water Dock, *Miscanthus* and *Eulalia*.

Water Lilies.—These are best planted in April, though, of course, planting may be done very much earlier. Before growth dies down completely, however, mark the spots where the plants are, otherwise it will be difficult to locate them. Large clumps that have to be curtailed may be pulled out now and re-divided if necessary, as it is much easier to see when the whole of the stool is removed.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Curbing Roots.—Where herbaceous borders are backed by hedges, Rose-covered trellises, or by climbers, the roots, if not checked periodically, rob the soil of its fertility. By cutting the roots almost close to the plants—I cut those of hedges perpendicular to the inner face—this does no harm.

How to Do It.—It is a very simple operation. A narrow trench the width of a spade and a few yards in length is thrown out at one end and deep enough to allow the spade being forced down to cut the lowest roots. A second stage of the trench is thrown into the first and the roots similarly treated, and so on to the other end, the open space being filled with the soil thrown out at the beginning of the operation.

More About Herbaceous Borders.—If there is not time to lift the plants, cultivate the soil and replant. The borders should be dug and some rotted manure worked in, reducing the dimensions of those plants which are overgrown. It harms no plant to cut its roots with the spade in the course of the work, and it is preferable to dig the border at this period rather than in spring, the labour involved being little more than that required to rake and clean off the surface rubbish which is buried in digging.

Hollyhocks.—Seedlings in too small pots to stand over the winter should be transferred to larger ones without further delay. Scarcely any water will be needed if the plants are wintered in a cool, dry structure, but roots will be formed and the plants much strengthened. Dusting with flowers of sulphur will keep the foliage free from Puccinia, which sometimes attacks it at this season.

Shrubs.

Planting.—Most of the replanting of choice shrubs should be finished forthwith, staking them as the work proceeds.

Their Hardiness.—Several notes have appeared on this point, and it may be remarked that a particular shrub may be cut to the ground or even killed in one particular spot, while in a more sheltered position and drier soil the foliage will not be so much as harmed. This, no doubt, is an effect of the quality of the roots, because it is found that a specimen of the same kind that has been recently transplanted weathers a severe winter when plants which have been undisturbed for years are either crippled or destroyed.

Shrubs that are Hardy.—*Choisya ternata* in various positions is much hardier than a common Laurel. *Cercidiphyllum japonicum* is also hardy, but does not colour so well here as in the South. *Nandina domestica* is not only hardy, but flowers annually. *Colletia* is also hardy and flowers sometimes bi-annual, and *Azaranic rophylla* fruits in the open, while *Piptanthus*, *Garrya* and *Carpenteria* are fairly hardy even in elevated parts. Probably these and other plants from warm climates become acclimatised in the course of years.

The Plant-Houses.

Cyclamen.—The old plants now in frames may be transferred to pits, where they will progress better. At the same time, if space is limited, they can be left for some time longer in a dry frame, giving them the minimum amount of water to make sure that the stalks of the flowers do not rot. See that seedlings are carefully watered, and yearlings coming into flower may have manurial aid.

Liliums.—Any unflowered speciosums still standing outdoors should be placed in a slightly warm temperature, in which the flowers will open kindly. Others that have finished growth should be stored in a frost-proof building and allowed to rest till the bulbs exhibit signs of activity in spring.

Dendrobiums.—Deciduous species which have finished growing should be placed in a cool, dry house where they can get a long rest. The stronger-growing kinds usually want staking anew, but the number of stakes may be considerably reduced by tying a number of growths to one stake or to each other.

Schizanthus.—These will be in a condition for repotting into 5-inch or 6-inch pots. Clarkias require much more root space, but if not forward enough they may have an intermediate shift. These succeed very well in an ordinary Carnation-house, the temperature and manner of ventilation suiting them very well.

The Fruit-Houses.

Bottling Grapes.—Some of the Vines, such as Muscats and Alicantes, which are fully matured, can now be relieved of their crop. A dry room where the temperature can be kept from varying without the employment of much firing suits them very well. Frequent examination of the clusters is important to keep damp from spreading from berry to berry.

Pot Trees.—Those not yet potted up for the year should now be either repotted or surface-dressed and the drainage renewed; then placed out of doors as advised in a previous calendar for Peach trees. As soon as all the foliage is off, they may be sprayed to destroy any parasites and their eggs.

Peaches.—The latest fruits will ripen all the better with pipes heated to sweeten the atmosphere and to keep the temperature about 45° to 50°, so as to ensure flavour. The fruits ripen very slowly, but must be frequently examined, and those approaching maturity removed and ripened off in a warm room.

The Vegetable Garden.

Cabbage.—The larger plants of the autumn planting will be improved by drawing a little earth up to the stems and loosening the soil between the rows of all. Wimmingstadt is now producing, and should be used up before the Drumhead section, which stands the winter better. Stir the soil well among Coleworts which are backward, and those that are turning in pull up with a twist so as to keep the quarter tidy.

Endive.—Where this vegetable is in request, enough to meet the supply for five or six days should be put into the Mushroom-house at intervals. Lifted with a ball of soil attached, they may be set close together on the floor of the house, and need no more attention till ready for use. The latest batch growing outside should be transplanted into cold frames.

R. P. BROTHERSTON.

Fynninghane, Prestonkirk, N.B.

TREES AND SHRUBS.

THE BEST SHRUBS FOR FORCING.

PEOPLE who wish for a good supply of forced shrubs for winter and spring would do well to commence their preparations without delay, for the best results are obtained from plants which are potted at once, because the roots are still active and the plants become well established before winter sets in. No doubt in many gardens this important work has already been done. Where alterations to shrubberies and beds of shrubs are contemplated, it is sometimes possible to select suitable subjects for forcing from among the surplus plants, but the most satisfactory results are usually obtained from plants which have been grown specially for forcing. The size of the plants required has, of course, to be taken into consideration, and when they are to be used for decorating large rooms, the bigger and older ones from the shrubbery have the advantage; but as a general rule well-grown nursery stock is quite satisfactory.

When shrubs are being grown specially for forcing, care is taken to foster the production of the maximum amount of flowering wood for the size of the plant; therefore all useless, weak branches are cut away during summer, so that the whole energy may be concentrated upon the production of good, vigorous shoots. In the case of Lilacs and a few other subjects, this thinning process has the effect of making the plants somewhat straggly in habit; that, however, cannot very well be helped if flowers are to be the first consideration. As a rule, it is as well to lift the plants from the borders, pot them at once, and then plunge them in ashes out of doors until required for use. Should a frosty time be experienced in winter, dry leaves or hay spread over the surface of the ashes makes it possible to remove the pots from the plunging material at any time when the plants are required for the forcing-house.

A great many shrubs are grown specially for forcing in some Continental nurseries, and they are sent to the British Isles in large numbers during autumn; but some nurserymen in this country make a speciality of growing shrubs for the work. Twenty years ago comparatively few kinds were considered suitable for forcing, but of late years many more have been requisitioned. Of those most suitable for the purpose, the following selection has been made:

Wistaria chinensis.—This is one of the most beautiful shrubs imaginable, for the large racemes of fragrant mauve flowers are borne with great freedom. Moreover, it is one of the plants which may be grown in pots and forced for several successive years.

Robinia hispida inermis is another excellent shrub for the purpose, for its large, rose-coloured, Pea-shaped flowers are very attractive.

Forsythia suspensa is, in a way, as valuable for greenhouse as it is for shrubbery decoration, for it forces easily, and may be had in flower from Christmas onwards. Large bushes lifted from a shrubbery blossom well.

Spiræas are also useful, such kinds as *arguta*, *confusa*, *prunifolia flore pleno* and *van Houttei* being the best. These are all white-flowered, and the blossoms are borne in profusion.

Prunus japonica flore pleno and *P. triloba flore pleno*, the former white, the latter pink, are popular shrubs which may be depended on to flower well; while any of the double-flowered

Peaches, more especially the red ones, are excellent when large plants are required. They may, however, be obtained as quite dwarf plants, but such are less showy than those of natural growth.

Staphylea colchica.—The flowers of this and *S. Coulombieri* come quite white when forced, and, as the inflorescences are large, well-flowered plants are very attractive. Although not generally forced, the double-flowered *Kerria japonica* is excellent for the purpose, while *Berberis Darwinii* may also be used. Various Crab Apples are grown as dwarf plants for forcing, such kinds as *Pyrus floribunda*, *P. Scheideckeri* and the double form of *P. spectabilis* being specially valuable.

Magnolia stellata, *M. conspicua*, *M. soulangeana*, *M. Lennéi* and *M. rustica* are all worth consideration, the first-named by reason of its glistening white star-shaped flowers, and the others on account of their large cup-shaped, fragrant blossoms.

Diervillas (Weigelas), such as *Eva Rathke* and *Abel Carrière*, blossom profusely if brought on gradually, but they object to violent heat in the early stages.

Lilacs of various kinds are very serviceable, those known as *Charles X.* and *Marie Legrave* being two of the best. When selecting Lilacs, care should be taken to choose those with a few strong growths, rather than those which are made up of a large mass of small branches, for the latter rarely bloom satisfactorily.

Deutzia gracilis has long been popular for spring use on account of its graceful habit and white flowers. *D. Lemoinei* is also useful, while the various varieties and hybrids from *D. discolor purpurascens* may be requisitioned.

Azaleas.—Of the various hardy Azaleas, those of the mollis class are perhaps the best, although they lack the fragrance of the American kinds. For quantity of flowers and richness of colouring they are, however, unequalled.

Evergreen Rhododendrons need to be selected with care, for all do not force equally well. Probably the best of all for forcing is *R. nobleanum*, for it may be obtained in flower from Christmas onwards. Any kinds which bloom moderately early, however, may be tried; but it is not advisable to force any of the late May and June flowering sorts. Dwarf growers, such as *R. præcox* and *Rosy Bell*, are excellent for the work.

Other shrubs, such as *Kalmia latifolia*, *Zenobia speciosa*, *Hydrangea paniculata grandiflora* and *Cytisus præcox*, are also available, but they cannot be depended on to give such good results early in the year as those previously mentioned. W. D.

THE EDITOR'S TABLE.

October Flowers from a Sussex Garden.—A box of hardy flowers and berried shrubs kindly sent by Mr. J. Comber of The Gardens, Nymans, Handcross, Sussex, serves to remind one of the many beautiful subjects that may be grown in the open for October effect. Among the plants sent were *Habrothamnus elegans*, more correctly known as *Cestrum elegans*, and usually given a position under glass; *Eugenia apiculata*, sometimes met with under the name of *Myrtus Luma*—the sprays sent were literally smothered with creamy white flowers; *Polygala mixta*, with Heath-like foliage and small pink flowers; *Billiarderia longifolia*, with shiny purple-black berries; *Eupatorium weinmannianum*, with large heads of dull pink flowers; the sky blue *Lathyrus pubescens*;

Euonymus alata, with bright red autumn foliage; *Cyrtilla racemiflora* and *Erica ciliaris*, completing a most interesting collection, particularly for the time of the year.

Carnations from Enfield.—Messrs. Stuart Low and Co., Bush Hill Park, Enfield, send flowers of some of their new Perpetual-flowering Carnations, which are very good. Among them we were particularly pleased with *Cinnabar*, a very fragrant flower of cinnabar red colour; *Benora*, a large, exquisitely-shaped variety, white, striped scarlet; *Rosette*, bright cerise, with large, full flowers; and *Baroness de Brien*, a glowing shade of salmon pink. This last is a particularly large flower. All those named have long and very stout stems, and the calyces are sound.

Primulas from Duns.—Dr. Macwatt sends from his garden at Duns, N.B., a wonderful collection of Primulas for the time of year. Among them were some particularly fine examples of the gold and silver laced Polyanthuses that used to find such favour with florists. Primroses of nearly all colours, including some extra good blue ones; a number of beautiful double varieties, together with such species as *Julie*, *Listeri*, *vittata*, *japonica* and *altaica*, all added their quota of beauty and interest to this contribution. We must also mention the fine forms of *P. obconica* that Dr. Macwatt included, the white and blue varieties being particularly pleasing.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

TO DESTROY BEARBINE (J. H.).—If your ground is fairly clear of everything else, you cannot do better than trench it and pick out every piece of the weed you can find. Pieces are sure to be left, but a sharp look-out must be kept, and as soon as any growths appear above ground they must be destroyed. By repeatedly hoeing the weed it can be killed in time; but you cannot be sure that you have cleared the ground for several years, whereas by trenching and picking out the underground stems you make sure of killing by far the greater proportion. When it is growing in hedges or among shrubs, the only plan is to keep pulling the shoots up as they appear above ground. This will in time weaken and eventually kill the weed.

MARCHANTIA AMONG ALPINE PLANTS (J. J. R.).—You ask whether "some chemical would eradicate this without injuring alpine plants," and the answer is "No!" What would be death to one of the lower forms of vegetable-life would be death also to other forms a few degrees removed. If this vegetable pest is present to an injurious extent among alpine plants, we can only suggest two ways of coping with it, viz., preventing its maturing spores giving a fresh crop, and frequent disturbance, using a pointed stick to dislodge it, and burn it. Should it exist in any get-at-able place, a strong solution of salt and water might be applied with a small paint brush, but the solution must not touch the plants or be in sufficient volume to reach their roots. Generally speaking, its presence is indicative of much moisture or shade; but as you say it thrives in sun or shade, you appear to be badly circumstanced. Try the pointed stick arrangement and persevere. The plant detests interference, though not easily got rid of.

ROSE GARDEN.

ROSE FOLIAGE BLIGHTED (*H. G. R.*).—Your Roses are infested with thrips and Rose sawworm. They should have been sprayed earlier with some good insecticide, such as nicotine wash. We should advise cutting a lot of this blighted foliage off and well spraying the plants afterwards with a solution of Cyllin Soft Soap, obtained from Messrs. Jeyes of Cannon Street, London, E.C. Or you could make a strong solution of Lifebuoy Carbolic Soap and spray well with this on the upper and lower surfaces of the foliage. Give the plants a mulching of 2 inches or 3 inches of well-decayed manure or spent Hoops. Next May give them a good deluging with plain water, and a few days afterwards with some good liquid manure.

PROPAGATING THE PERNETIANA ROSES (*Northants*).—The Pernetiana Roses are best budded upon the seedling Briar stock, and upon the hedge Briar for standards. The distinguishing feature of this new tribe is that they possess much of the Briar-like nature of their first parent, Soleil d'Or. This, as you may know, was obtained from a cross between the Austrian Briar (*Rosa lutea*) Persian Yellow and a Hybrid Perpetual Rose, Antoine Ducher. The originator of the tribe, M. Pernet-Ducher, has used this Soleil d'Or and seedlings from it in creating the Pernetiana group, the seed-parents being in most cases various Hybrid Teas. For instance, Rayon d'Or was raised by crossing Melanc Soupert with Soleil d'Or. Those of the tribe that favour the Soleil d'Or most in their erect habit are Juliet, Soleil d'Angers and Beauté de Lyon, while the following have more of the Hybrid Tea character, although distinctly blended with the Briar nature: Lyon Rose, Arthur R. Goodwin, Rayon d'Or and Viscountess Eufield. All of these are very fine, and well worth adding to any collection.

DESCRIPTION OF RAMBLER ROSES (*P. H. T.*).—It is always most difficult to put on paper a true description of any Rose, and especially with ramblers, whose peculiarity it is to change in appearance almost daily. Now, in comparing the following Roses with Dorothy Perkins it must be admitted that soil and situation will make a great difference in colour, size of bloom and truss. Taking the Roses in the order you have named, Minnehaha is quite a deep rose pink in colour, the flowers much larger than Dorothy Perkins, and the truss much larger and longer. The growth is very vigorous, the foliage larger and of a paler green, and the time of flowering about the same. Debutante flowers quite two weeks earlier with us. Its blossoms are a very dainty bluish pink, double and well shaped, but the clusters are rather small. It has the merit of flowering again as does Dorothy Perkins. Lady Gay is a heavier pink, almost a salmon pink; the flowers are much larger, and the clusters are also larger. There is not so much bluntness as in Dorothy Perkins when fully out, but it does not flower much a second time. It is about eight days earlier than Dorothy Perkins. The Farquhar is of a rose pink colour something like Minnehaha, but the flowers are smaller, and the clusters will often contain blooms nearly white. It is a variety we can well do without. Dorothy Deaconson, Christiana Carle and Lady Godiva are practically all alike. If you have neither, you should obtain Lady Godiva. It is a very lovely soft flesh pink colour, and flowers about the same time as Dorothy Perkins.

THE GREENHOUSE.

AURICULA (*J. B.*).—There is no fungus present on the Auricula, nor can we find any insect. Have the plants been kept too moist and warm?

HIPPEASTRUMS (*E. R. P.*).—The most probable cause of your Hippeastrums failing to flower was that the bulb was insufficiently ripened, for had the flower-spike in embryo been contained within the bulb, it should have developed under the conditions named by you. Doubtless the same cause applies to the second and smaller bulb. In order to ensure a display of bloom, it is most essential that the bulbs are well ripened; hence they should, during the latter half of the summer, be fully exposed to the sun. They must, however, be kept regularly watered till the leaves die down, when less must be given, and throughout the winter discontinued altogether. If you have no greenhouse, a sunny window is a good place in which to ripen the bulbs.

CARNATIONS (*C. A.*).—There is no distinct Latin name for the two sections of Carnations named by you, as all of the different forms of Carnations now in cultivation have originated from one species, namely, *Dianthus caryophyllus*, a native of Europe. The Malmaison Carnation is of a sturdy habit of growth, with very large, irregularly-formed flowers, which are deliciously fragrant. It is the most particular in its cultural requirements of all the Carnations. The American varieties, on the other hand, are characterised by a free habit of growth, and bear throughout the greater part of the year fine showy flowers on long stalks. Though large, the blooms of these are in size not equal to those of the Malmaison, but they are of better shape, while in most of them the edges of the petals are more or less toothed. The varieties of this section vary a good deal with regard to their fragrance, some having very little, while others are sweetly scented.

GLOXINIAS (*Mary Jane*).—The reason of your Gloxinias behaving in the way indicated is, no doubt, owing to the fact that they have been subjected to too much heat and moisture, and are consequently unable to stand up against the change in temperature. You speak of growing them in a hothouse and then shifting them into a house which is also heated. This would I suggest that the house in which they are grown must be kept very hot indeed, for Gloxinias

at this season require but little fire-heat; in fact, good plants can be grown at this season without any artificial heat whatever, provided care is taken to shut up the house early and thus husband the sun's rays. We should advise you to grow your plants altogether under harder conditions (not altogether without fire-heat), and then you are not likely to be troubled in the way described. One thing, however, to bear in mind is, whether grown hot or cool, they must be shaded from the sun's rays during the hottest portion of the day throughout the summer months. As your plants are so weak, you may remedy matters somewhat by supporting the blooms with slender, inconspicuous sticks, tied with dull green thread.

FRUIT GARDEN.

APPLE TREES ATTACKED (*R. J. G. R.*).—The Apple twigs have been attacked by woolly aphis, and probably by canker. The trees are, there is little doubt, attacked in the stem, and the early spots should be cut out and the wounds painted with Stockholm tar or lead paint.

VINE LEAVES INFESTED WITH THRIP (*H. G.*).—The leaves are badly infested with thrip. It is difficult to kill without at the same time injuring the Vine foliage. The only way is to fumigate with Tobacco paper or rag, or with XL Alf; or, if you have time and patience, sponge the leaves of the Vines with warm water and soft soap. If you fumigate, you will require to do so on three successive evenings before you can get rid of the pest. Be careful not to fumigate with too strong doses of XL Alf.

BLACKBERRIES (*T. E. W.*).—If you do not grow the Loganberry, you should do so. It is the strongest grower and the heaviest cropper of all the Bramble type. It is a cross between the Raspberry and the Blackberry. The flavour is not over-sweet, even when quite ripe, but it is grand for tarts and jellies. Another new Bramble berry you should try is the Newberry, also the Phenomenal and the Hailshamberry. The best pure Blackberry is Rubus laciniatus, or Parsley-leaved as it is commonly called. This is a good grower, crops heavily, and the fruit is large and of good flavour. The bushes should be planted 10 feet apart.

GRAPES AFFECTED BY MILDEW (*Borough*).—The sample of Grapes sent is badly affected by mildew. It is a pity, as the Vines are evidently well grown and the bunches good in size and berry. There is nothing better than to dredge the affected parts over thickly with flowers of sulphur, leaving it on for twenty-four hours, and then syringing off with clear rain-water. Once Grapes are attacked by mildew, the marks cannot be eradicated; but the above treatment will kill the mildew. No one knows for certain the causes predisposing Vines to this disease; but we believe that injudicious ventilation in cold weather is one fertile cause. Be sparing of front air when cold winds prevail.

ABOUT PEARS (*Ilex*).—No: the pollen was not lost, but it is quite possible that the lack of fruit is due to want of pollen, for Doyenné du Comice is better for pollen from another variety altogether. In the case of this tree, it might be well to place near it a branch of another variety at flowering-time, so as to get the pollen carried on to it. Yes; prune your gridiron-shaped tree in the way suggested. "Pinching out" means pinch off by means of the finger and thumb. The small Pear is attacked by the Pear scab. Spray with copper sulphate during winter (1lb. to twenty-five gallons of water) and with half-strength Bordeaux mixture as soon as the petals fall, and again in June. The other Pear is affected with the same disease.

PEACH SHOOT DISEASED (*H. F. C.*).—The shoot is badly infested with black fly in all stages of growth. If you shake the branch over a piece of white paper, you will easily see the insects crawling about. The way to kill them is to steep the branches in the following emulsion of soft soap. Until these pests are got rid of, it is impossible for the foliage to grow. Take a claretglassful of soft soap and the same of paraffin. Mix in a quart of warm water. This will form a creamy emulsion. Add another quart of water, and the emulsion will be ready for use. Apple Mannington's Pearmain is a good Christmas dessert variety and a fairly constant bearer. Perhaps the trees want root-pruning.

KITCHEN GARDEN.

TOMATOES (*G. H. P.*).—There is no fungus disease present in the Tomatoes. They have not had a sufficient supply of potash. Give a little sulphate of potash in the water used for watering at intervals of a week.

TOMATO PLANTS NOT FRUITING (*Miss Hall*).—The Tomato is a sun-loving plant. It cannot be satisfactorily grown in a shady position, and we think that the chief reason for your plants not bearing as they ought is due to the shade of the fine foliage. The best thing you can do another year is to cut the plants down to the second leaf above the last cluster of fruit, and then top-dress the plants with the following compost: To a bushel of new, sweet loam add half a gallon of well-decayed farmyard manure, after passing it through a 1-inch-mesh sieve, and one pint of bone-dust, mixing them well together. Take away some of the old surface-soil and replace with the new compost, pressing it down hard. Having done this, remove the plants to a warm, sunny and sheltered corner of your garden out of doors. Here you will find they will soon make new, sturdy, fruitful growth and set their fruit easily, provided the plants are well looked after in the way of watering, &c. Confine the new growth to one shoot (one stem) and pinch off laterals. The plants may not ripen all the fruit before cold weather sets in, but they can then be taken under glass to finish the process.

MISCELLANEOUS.

SULPHATE OF IRON (*J. W.*).—We believe there is no material value in this article excepting that it enriches the colour of Roses, and also, as a corresponded suggested in our columns, it may strengthen the scent. Artificial manure may be safely kept for some months if it is in a rainproof shed. It need not be kept airtight.

INJURY TO HORSE CHESTNUT LEAVES (*Mrs. G. C.*).—We regret that we are unable to say what is the cause of the Horse Chestnut leaves being damaged so badly, unless they are in the way of fumes from a chimney, but perhaps you will send us more specimens when the injury first makes itself evident next year.

PRESSING COLOURED LEAVES (*H. W.*).—Some plants with highly-coloured foliage cannot be dried very well to retain their colour, and the same refers to flowers. Quick drying is most likely to prove successful. Porous paper should be used, and it should be changed frequently, taking care to dry it thoroughly after being in use. There is no other practical way of drying plants, and the loss of colour cannot be helped, though for many years people have looked for a way to avoid it.

INSECTS FOR IDENTIFICATION (*T. F.*).—The insects are aphides, and apparently the common dolfio or black fly of the Peach and Cherry. They had been attacked by a fungus, which preys upon them and destroys them; this accounts for their peculiar fluffy appearance. They will, if all are like these, not need destruction, for they are already naturally destroyed, but if not, the Peach, if under glass, requires to be fumigated. If in the open it should be sprayed with a nicotine preparation.

AQUARIUM (*U. S. L.*).—We know of no "ornamental shrub that would be always green" and likely to succeed in your conservatory pond. There are Water Lilies, Grasses, Bushes and other forms of vegetable-life which would be quite happy if partly or wholly submerged; but few of these would be evergreen, and none capable of creeping round the walls. Cement is hard, impervious and unsympathetic to plant growth, hence any draping of the sides of the tank or pond should be done from the surface margin of the same. Viewing your enquiry in detail, we doubt our ability to assist you as it stands, and think possibly you might prefer to give us some fuller particulars. Among these, the minimum temperature of the conservatory would be of some importance.

FAIRY RINGS ON LAWN (*H. C. D.*).—It is very little use trying to kill the fungus which forms fairy rings with sulphate of iron on the dry slopes you mention, for to do any good it is necessary to soak the ground to a depth of 9 inches or 12 inches with the sulphate of iron solution, and from what we surmise that is not possible. A good plan to adopt is to remove the soil from the centres of the diseased areas to 6 inches beyond the outer margins and to a depth of 12 inches, and fill up the trenches with fresh soil from some other position. The soil removed may be used on cultivated land, but not on grass land. Whether the banks should be removed bodily is a point we are not in a position to decide, for that depends solely on the character of the surrounding ground. The fungus will not spread from the inner parts of the circles, therefore there is no necessity to remove soil from those parts.

VARIOUS QUERIES (*Ignoramus*).—Your plants of *Primula malacoides* would appear to have devoted more of their energies to the production of foliage than of flowers. As, however, they continue to bloom throughout the autumn, winter and spring, it is more than possible that this defect will be naturally remedied and the plants give perfect satisfaction later on. After the Saxifrage has flowered, it should be left alone on the rockery, and not lifted and then taken under glass. The side shoots, when sufficiently advanced, may be taken off and potted into small pots, and in this way the Saxifrages in question can be increased. After potting, these offsets are best protected in a frame. If a particularly good offset develops, it may be allowed to remain to in time take the place of the present plant. Your better plan will be to replot the Lilium named as soon as the flowering stems die down, and keep them during the winter in a cold frame. Till growth recommences they will need just enough water to keep the soil slightly moist, but no more. Some Lilies are far more prone than others to remain dormant the first season after planting. Those least affected by removal are the species which produce a large quantity of roots at the base of the flower-stem, such as *Lilium croceum*, *L. davuricum*, *L. auratum*, *L. speciosum* and *L. longiflorum*. These roots serve to support the flower-stem while the roots at the base of the bulb are becoming established. Some species, on the other hand, have stout, deep-descending basal roots and very few stem ones. These need at least a season to become established before they flower well. To this class belong *Lilium Martagon*, *szovitzianum*, *chalecedonium* and others. Even those that as a rule flower well the first season after transplanting often remain more or less dormant if they are moved late in the season. The *heavilleas* can be readily grown in deep pots, and are then very useful when in flower for the decoration of the greenhouse. Pot them late in the autumn when dormant. We cannot understand your plants of *Erigeron aurantiacus* going off in the winter in the way described by you. Perhaps the drought last autumn was too severe; but, even then, that would not hold good the preceding year. We have, however, noted that this *Erigeron* often does better where partially shaded than in full sun. We should advise you to again leave *E. aurantiacus* outside during the winter, and if in a dry, well-drained spot, *E. mucronatus* as well. The mauve *Erigeron* mentioned by you is doubtless *E. speciosus*.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Chrysanthemums in London Parks.—For some years past the London County Council has provided rich displays of Chrysanthemums in a number of the parks that come under its control, and, judging by the crowds of visitors, these are very highly appreciated. Exhibits are now open at the following parks: Battersea, Victoria, Southwark, Finsbury, Brockwell and Waterlow.

Tropical Fruits at Covent Garden.—During the past few weeks considerable interest has been taken in some consignments of fruits of *Monstera deliciosa*. These somewhat resemble Pine cones in shape, and the flavour may best be described as a mixture of Pineapple and Peach. The fruits under notice come from Madeira. The plant is a tropical climber, the large leaves of which are perforated with holes and the margins much lacerated. Specimens can be seen in No. 1 House at Kew, near the main entrance.

An Autumn-flowering Snowdrop.—*Galanthus Olgae* is once more on the market, and was shown at a meeting of the Royal Horticultural Society a short time ago. It is not so reliable as *G. cilicicus*, which is rather later, and has been lost several times by some experienced cultivators of the Snowdrop. It is rather a delicate grower, and has small, slender growth. The flowers are much the same as those of the common *G. nivalis*, but it blooms in October. It was found originally on Mount Taygetus in Greece.

The Rose Garden of Europe.—It is interesting to note that one of the chief industries of Bulgaria is the cultivation of the Rose for the purpose of manufacturing attar of Roses. The vast area of fertile land lying between mountain ranges in the neighbourhood of Kasanlik is devoted entirely to the Queen of Flowers, and is very appropriately known as "The Valley of Roses." It is the Damask Rose (*Rosa damascena*) that is so extensively grown for the distilleries, both pink and white varieties. A prettier sight than Rose-picking in the early hours of a June morning it would be hard to describe, and this within a few hours' journey to the north-west of Adrianople, now the scene of war with all its terrible associations. From its vast plains and valleys of Roses this Balkan kingdom has earned for itself the title of "The Rose Garden of Europe."

The Persimmon, or Date Plum.—It does not appear to be widely known that the interesting shrubs *Diospyros*, which produce fruits known as Persimmons and Date Plums, are really hardy—at all events in Southern gardens of this country. Three species are mentioned in the "Kew Hand List of Hardy Trees and Shrubs," viz., *D. Kaki* of Japan; *D. Lotus*, said to be naturalised in Southern Europe; and *D. virginiana*, the Persimmon of the United States. By way of proving its hardi-

ness, one of these species is now producing a crop of fruits on a wall facing south at Kew. It is curious to note that in their native habitats some species of *Diospyros* yield the valuable wood ebony. The sap-wood is white and soft, and the heart-wood hard and black.

Veronica subsessilis.—In the entire range of the hardy herbaceous Veronicas there is no species of such merit as this, none so rich or decided in colouring, and, happily, none more amenable to good cultivation. That is to say so unique a subject is worthy of every care, and if given generous treatment will repay it a hundredfold in August and September. This fine Japanese species is quite unique, not only in the intensity of its rich deep violet flowers, but in a flowering and vigour of growth which separates it from all others. It is a plant to be made much of.

A Good Rock Garden Shrub.—The value of low-growing shrubs in the rock garden is now fully appreciated by those who wish to have such a garden bright over as long a period as possible. Unfortunately, the number of shrubs suitable for the purpose is not large; hence *Cotoneaster humifusa*, a new Chinese species, is likely to prove a most welcome addition. It has a low, trailing habit, is perfectly hardy, and just now freely bedecked with scarlet berries. Planted so that its shoots could hang closely suspended over a large boulder or miniature precipice, it would make a fine effect in the rock garden at this season.

Exhibits from School Gardens.—Although there are thousands of school gardens in the country, it is seldom that exhibits of the produce grown therein by the scholars are seen at our London shows. At the meeting of the Royal Horticultural Society held last week, visitors were able to gain some insight to the crops grown in such gardens by an exhibit from the Purfleet School, Essex. Compared with the high-class fruits usually staged at these meetings, those comprising the exhibit under notice were, naturally, somewhat commonplace; but the exhibit served to show that instruction at the school is carried out on proper lines. More exhibits of this kind would tend to increase public interest in school gardening.

Iris Snow Queen.—This very beautiful Iris is gaining ground more slowly than its merits deserve, and intending purchasers of new plants for another year should not omit it from their lists. It is understood to be a hybrid, and to have some of the "blood" of *Iris sibirica* in its veins. It is an easy subject to grow, but evidently likes a fair amount of moisture, and by the side of a pond or stream looks remarkably ornamental. It is neater in its growth than the white varieties of the Siberian Iris itself, and has larger flowers of much greater substance, the white being so pure, also, as to well entitle the plant to the name of Snow Queen.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Zauschneria californica.—The note in your issue for October 19, page 525, reminds me that one hears constant grumbles that this plant will only flower in very exceptionally hot seasons, and that it is not generally known that the variety *californica* not only has a much longer flowering period, but produces bloom freely even in such a dull season as this last. It has paler and brighter green foliage than the type, and the flowers are of rather a lighter shade of scarlet. I have grown it here on the rock garden for some fifteen years, and though left in the same position all the time, it has never failed to make a good show each season from July till severe frosts cut it down.—E. A. BOWLES, *Waltham Cross*.

New Zealand Shrubs.—For the information of your correspondent *Mona Mackay*, page 539, October 26 issue, I may say that the crimson-flowered *Manuka*, *Leptospermum scoparium nicholii*, is a seedling variation from the common *Manuka*, a troublesome weed, not only of New Zealand, but also of many parts of Australia. There is an older red-flowered form known as *Chapmannii*, which was first found in the South Island of New Zealand, but the variety *Nicholii* is much deeper in colour, being, in fact, a rich ruby crimson, while the foliage is much darker tinted than in the common kind. The original plant of the variety *Nicholii* was, half-a-dozen years or so ago, discovered growing on the sandhills a little north of Christchurch, and was taken in hand by Messrs. Nairn and Sons of Christchurch. Since then it has been fairly well distributed, and has been grown in this country for the last three or four years.—H. P.

The Twelve Best Climbing Roses.—I had no desire to administer "a dressing" to "G. B. W.," but as "a dressing" is admittedly (whatever form it may take, pleasant or unpleasant) nourishment of some sort—for Roses—may I express the hope that the dressing, if it was one, may also prove of service to "G. B. W.," non-rosarian though he may prefer to call himself. He will forgive me if I say that in so doing I think he is libellous; at any rate, he is sportsman enough to have within him the makings of a first-class rosarian. And though he may at the moment remain "of the same opinion still," I am sure when he has obtained and grown the Roses I mentioned he will be "convinced against his will," and will then admit—I do not ask or expect him to do so before—that my twelve are better than his. I have written for *Marie Bret* and hope to flower it next season, and must conclude with a word of thanks to "G. B. W." for his courtesy and the friendly tone of his note in reply to what he terms my somewhat caustic remarks, and with the further confession that, at any rate with reference to the Latin quotation, I must cry "Peccavi."—HERBERT E. MOLYNEUX.

Cyclamen neapolitanum.—I have just been proving how well it pays to give this plant (like hosts of other things) good cultivation. For many years it has been growing here on a rough bank in very poor soil. During the last few seasons we have annually lifted a number of the seedlings and panned or potted them up, mainly for purposes of stock. The compost used has been loam, mortar rubbish, decayed Cocoanut fibre and a

little cow-manure, and in this they have thriven splendidly. I have noticed that they have given good and plenteous flowers in these pots and pans, which, by the way, are always kept outside or in cold frames, and we have just been turning out the contents of pans planted two and three years for purposes of replanting. We find large, healthy corms, each with a mass of strong fibrous roots, and, in addition, a number of stout little seedlings much more vigorous-looking than those we collect on the aforesaid bank.—F. HERBERT CHAPMAN, *Rye*.

Autumn Bedding Effects.—Many beautiful combinations of colour come under review from time to time in *THE GARDEN*, from which amateur and professional alike derive much benefit. A combination that has much to commend it on the score of simplicity and effectiveness consists of a groundwork of *Pelargonium Souv. de Chas. Turner*, with pillar-trained plants of *Swainsona alba* at intervals of 3 feet or 4 feet between, and, if the bed is a large one, a broad belt of *Veronica Andersonii variegata* enhances the effect. The *Swainsona* is a bedding plant of sterling merit, and flowers profusely from planting-out-time in May right up to the advent of frost.—THOMAS SMITH, *Coombe Court, Kingston Hill*.

Reinette Apples.—Your correspondent "A. T. C.," page 510, October 12 issue, raises an interesting point *re* the name *Reinette*. The use of names such as *Reinette*, *Pippin* and *Calville* has in this country been so carelessly treated that they fail to convey any special significance. In France and Germany, however, greater exactitude has been used, and they are applied with some system. The *Reinette* class has formed a division of most of the natural systems of classification, due to German experts, and in France the term is confined to a distinct and similar type of fruit. The character of the flesh is the basis of this group, and it may be said that all Apples that go leathery when kept too long or gathered too early are *Reinettes*. If we take the *Blenheim Orange* as a type, this particular characteristic will be realised. It is much to be regretted that these words, which should be descriptive of a class, should have been so recklessly applied, as they form a rough basis for grouping together varieties of similar qualities. The etymology of the word has been the subject of many suggestions. Its first recorded appearance is in the "*Seminarium et plantarium fructiferam*" of Charles Estienne, published in 1540. Various derivations have been put forward, including *ranette*—a diminutive from *rana*, a frog—on account of its spots, and that of Hogg quoted by your correspondent. The *Oxford Dictionary*, however, decides in favour of a derivation from *reine*—*reINETTE*, a little queen, as in our own Apple the *Queening*. I am aware that Hogg would derive this last from *coin* or *quoin*, a corner or angle, but I do not know of any philologist having accepted this suggestion, and the *Winter Queening*, one of the oldest of sorts bearing this name, is not by any means conspicuously angular.—E. A. BUNYARD.

Campanula Zoysii.—A note on this plant, together with a fine illustration which appeared some little time since, inspires me to a few more remarks on this very beautiful species, which this year I have for the first time made intimate acquaintance with in its own home. There is no wonder that *C. Zoysii* should prove so surprisingly (for it looks so frail and miffy) easy and robust under almost any reasonable conditions of culture with us, whether in soil or moraine, for, though

by nature a plant of high calcareous crevices, it is so vigorous a species that it will seed down into river shingles and there grow into enormous masses with a readiness that would certainly not be shown by *C. Raineri* and *C. morettiana*. For, like these two species, the one from the high Bergamasque limestones, and the other from the Dolomitic (I know of no high alpine *Campanula* that is non-calcareous—*C. excisa* and *C. Elatines* are from lower elevations and conditions), *C. Zoysii* belongs to limestone crevices high up in the cliff faces of the Carnic and Karawanken ranges, but locally as abundant as *C. morettiana*. It should presumably be in flower by August, and yet, in both high stations and I w, it was still in bud on August 25 of this year, with only a rare blossom open here and there. So what it means to do about seeding this season I cannot think. Nothing could well be more exquisite than its bulging and puckered up little bells of delicate pale blue. There is also an albino of extreme rarity and beauty. When it grows in cliffs, it affects the cracked rock in which *C. Raineri* can be found, rather than the stark and flawless precipices from which it is so terrible a task to extricate *C. morettiana*. But while it is even easier and heartier to grow than *C. Raineri* (being, indeed, by far the easiest of the alpine *Rock Harebells*), it is true to say that it shares *Raineri's* fascination for slugs.—REGINALD FARRER.

Lilium giganteum in Wigtonshire.—When on a recent visit to *Lochinch Castle*, the grandly-environmented residence of the Earl of Stair, Viscountess Dalrymple showed me in her famous wild garden, in a shady wood behind the Castle, an imposing specimen of *L. giganteum*, a native of the Central Himalayas, which, while reaching a height of 13 feet, had in the season of full floral beauty no fewer than sixteen enormous tunnel-shaped, ivory white flowers. I have heard of this great Lily attaining in two instances—in a garden near *New Galloway* and at *Cavens Gardens* in *Kirkbean Parish, Kirkcudbrightshire*—to an almost equally commanding elevation. I have also learned that at *St. Mary's Isle*, near *Kirkcudbright*, the former residence of the Earls of *Selkirk*, the Himalayan Lily has sometimes assumed commanding dimensions. But, so far as my personal observation is concerned, the *Lochinch Lily* beats the record, at least in Southern Scotland. Indeed, I have never heard of it anywhere in Great Britain attaining in an equally shady situation to a greater height. I may also, perhaps, be permitted to add that *L. giganteum*, whose culture is not exacting (if the soil is sufficiently fibrous to promote drainage and adequately fertile to inspire vigorous growth), is usually perpetuated by offsets, which it throws out for this special purpose contemporaneously with the decay and gradual extinction of the great flowering bulb, which is undoubtedly exhausted by this supreme effort, rather than by the mere creation of its massive flowers. Sir *Herbert Maxwell*, Lord-Lieutenant of this county, who is an earnest horticulturist and accomplished botanist, grows it extensively from seed at his beautiful residence of *Monreith*. It may be imagined how protracted is this evolutionary process when it is remembered that the largest offset obtainable takes at least four years to build up a full-sized flowering bulb. It is sufficient to render our horticultural patience, in the memorable words of *Matthew Arnold*, "too near neighbour to despair."—DAVID R. WILLIAMSON, *Manse of Kirkmaiden, Wigtonshire, N.B.*

Zephyranthes candida as an Edging.—Some weeks ago I read with interest a note in *THE GARDEN* about this beautiful little bulbous plant being used as an edging. The enclosed photograph shows it used in this way. The white flowers are very pleasing in autumn, and the green foliage makes a delightful edging. It appears to like soil that is well drained and of a rather sandy character.—E. M. D.

The Newer Hybrid Perpetual Roses.—I agree with my namesake, page 519, that the list he gives of newer varieties is a meagre one. It had better be that than a longer list of inferior sorts. I am sure Rose-lovers will have confidence in the selection he gives, because they know his recommendations are the result of practical experience. There is one sort I would like to add, and which he probably overlooked, viz., Commander Jules Gravereaux, sent out by Croibier in 1909. It may not be an exhibition Rose, perhaps, but that is not demanded of all Roses. The blooms are large, and the exhibitor would probably say they are too "rough." The petals are frilled, reminding one greatly of a Chinese Pæony. In colour it is a desirable velvety red, shaded maroon, and, what is very important, it is distinctly fragrant, which so many new Roses are not. I would like to emphasise all that is said about Gloire de Chedane Guinoisseau, because I consider this one of the most meritorious varieties sent out for many years. I have told scores of nurserymen to prepare a large stock of this variety, as there is certain to be a run on it. One of the dwarf plants I put in last November gave me ten handsome blooms during the months of June and July, as well as more from the second growth made later. Can Mr. Molyneux tell me where Hybrid Perpetual Roses leave off and where Hybrid Teas begin? What is the strict definition of the two, I wonder? —E. MOLYNEUX.

FORTHCOMING EVENTS.

November 5. — Royal Horticultural Society's Meeting and Special Exhibition of Orchids (two days) at Vincent Square, Westminster. Lecture on the first day by Miss Edith Saunders on "Double Flowers." Orchid Conference on the second day. Bournemouth Flower Show (two days). Chelmsford Chrysanthemum Show (two days). Southampton Chrysanthemum and Fruit Show (two days). Scottish Horticultural Association's Meeting. Birmingham Chrysanthemum Show (three days). Hayward's Heath Chrysanthemum Show (two days).

November 6. — Bath Gardeners' Debating Society's Chrysanthemum Show (two days). Dulwich Chrysanthemum Show (two days). Northampton Chrysanthemum Show (two days). Wandsworth Chrysanthemum Show (two days). Wargrave Chrysanthemum Show.

November 7.—Exeter Chrysanthemum Show (two days). Newport Chrysanthemum Show. Linnean Society's Meeting. Chrysanthemum Show at Stoke Newington (two days). Bury and West Suffolk Show (two days).

November 8.—Chrysanthemum Shows at Epsom, Nottingham (two days) and Lowestoft (two days).

November 9.—Burton Chrysanthemum Show.

THE GREENHOUSE.

NOTES ON CHRYSANTHEMUMS.

NOVEMBER WORK.

THE results of the work of twelve months, and in some cases more than that period, will now be seen in thousands of gardens in the country. The large blooms will be in evidence, whether they are intended for exhibition or for the embellishment of the conservatory. Specimen plants, bearing from nine to two dozen blooms each, are very effective and useful in the greenhouse, and for placing

ZEPHYRANTHES CANDIDA, AN AUTUMN-FLOWERING BULBOUS PLANT, USED AS AN EDGING.

in porches and corridors temporarily. Inexperienced cultivators are sometimes over-anxious about the production of large blooms, and often give the plants too many stimulants and in doses that are too strong. They rely a great deal on nitrate of soda and sulphate of ammonia, which kill many roots and check the growth of the bloom petals. Furthermore, they cripple the growth of suckers, and thus spoil the chance of procuring healthy cuttings for another year. After the blooms have three parts developed, the plants need only clear water of the same temperature as the house. Sufficient only is required to prevent the leaves flagging. So treated,

plants in greenhouse and conservatory groups will last a long time in a fresh state and retain their lower leaves. The blooms will not damp off unduly if a little shading is applied when the sun shines brightly.

Shading and Ventilation.—White, yellow, primrose and blush coloured flowers do not fade or damp off as soon as the bronzes, chestnuts, crimsons and buffs. Some light material should be placed over those that fade the soonest and last in a fresh condition only a short time. If grown in low houses, more shading is necessary when the sun shines brightly than when the plants are grouped in high structures. The ventilation of the house is a matter of great importance, as the plants must have plenty of air without being subjected to cold draughts. More air should be admitted through the top ventilators than the side ones. The latter must be kept closed except on very fine days. The top ventilators must be kept open night and day except in foggy weather, and every night the pipes should be warmed to ensure a free circulation of air.

Grouping for Effect.—When commencing to arrange a group of plants, the owner must always place the tallest plants at the back and finish with the dwarf ones in the front; but the appearance of the blooms must not be too formal. An undulating surface will look best and be the most interesting. Avoid overcrowding.

Plants to Flower at Christmas.—These are of great value because they provide the cultivator with blooms for cutting and other purposes at a season when flowers are scarce, few being obtainable except from plants that are forced. Chrysanthemums need no forcing. When the right varieties are grown, they will bloom at the required time if kept safe from frost and in a fairly dry atmosphere. In order to strengthen the flower-stems, keep the buds near the glass and only apply stimulants every third watering until the colour of the florets can be seen; then feed oftener for a time. A top-dressing of rotted manure and fibrous loam, mixed, will greatly benefit the plants.

Plants Lifted from Borders.—Before lifting the plants, the soil should be made quite firm all round them by treading. Then, with a clean, sharp spade, thrust well down, sever the roots on every side and about four inches away from the main stem. This will enable one to lift the plants with a good ball of soil and roots, for which a large pot, tub or other receptacle must be used. Make the new soil quite firm around the roots and give a thorough watering. The check given to such plants results in the loss of some of the bottom leaves, but the buds are not materially affected. At first daily syringings on fine days will do more good than the constant watering of the soil. If the foliage is maintained in a fresh condition, new roots will soon permeate the soil used; and, if ample ventilation be afforded, the buds will be sturdy and the flowers very satisfactory and useful, remaining in good condition for some time after frost has destroyed those left outside. AVON.

THE FLOWER GARDEN.

LATE FLOWERING TULIPS.

AS we all know, Mrs. Jarley of Living Works fame, whenever she came to such a figure as that of the Emperor of China, always gave us a bit of geography. "China," she used to say, "is divided into two parts; China proper and China improper. Of the first I know nothing whatever about, and the second we will not pause to discuss." So with these Tulips. They also are divided into two parts, but both are real, proper flowers; at least, we all say so when we have taken out our "florists' eyes" and put in those of ordinary mortals. There has been quite a little mania-time in Holland this year ever since the days of the "green sales" (that is, the plants as they are growing). I am glad, for it means that lovers of gardens all over Europe and America are beginning to appreciate Tulips at their proper value, and to realise what useful flowers they are to brighten up their beds and borders in early May.

The next ten days after these lines appear in print is the best time for planting; but Tulips, I find, are very accommodating in this respect, and I have had excellent results from bulbs which were not put in until mid-December. Perhaps, if it is not too much like carrying coals to Newcastle, I may remind my readers of the uses to which these late Tulips may be put other than those of filling beds or forming larger or smaller groups in borders.

First—and this is especially true of the Cottage section, with which, however, I must for this purpose couple one or two "species"—they are excellent for cutting. For this purpose they should be planted in beds in the kitchen garden, or else where the blooms are not wanted for outside decoration.

A VASE OF COTTAGE TULIPS. BULBS MAY BE PLANTED NOW.

Secondly—and this is only true of the Darwins and the Darwin-shaped yellow Cottage, such as Clio or Jaune d'Œuf—they lend themselves very well indeed for growing in pots to bloom, say, between March 15 and March 30. An ideal place in which to put these when in flower is on the floor of a winter garden or a smoking-room conservatory. Appended are three lists.

For Cutting.—These are for the most part varieties with long, slender stems and rather pointed flowers. In a word, they are graceful rather than handsome. Didieri, small pointed flower, bright red; Didieri alba, a pure white form of the preceding; elegans alba, pure white, of much substance, with a very fine "wire" edge of carmine, which never flushes the ground colour as in Picotee; Ellen Willmott, lovely soft citron yellow pointed petals; La Merveille, tall-growing, superb variety, a sort of orange carmine; Marjoletti, creamy white, with a rosy pink mark at the base of each petal; Mrs. J. Robertson, a yellow of a deeper shade than Mrs. Moon, and of much the same long shape; Mrs. W. O. Wolseley, a rich dark crimson; Pride of Inglescombe, a later, deeper coloured and larger Picotee; Picotee, pointed flower, white, edged rose—as it ages the colour gradually extends almost all over the petals; retroflexa, an ideal Tulip for cutting, soft canary yellow self, vase-shaped; The President, an exquisite shade of buff orange—very few flowers of this shade; and Walter T. Ware, by far the deepest shade of yellow of any Tulip. It has pointed petals. The illustration of Cottage Tulips admirably illustrates the adaptability of this section for vase decoration. I do not ever remember to have seen a better one. The flowers were arranged by Mr. F. Lilley of Guernsey.

For Pots.—Most Darwins may be grown successfully in pots. I give in this list another baker's dozen of some of the best of them and the yellowy Darwin-shaped Cottage varieties, which are also well adapted for this purpose. A single word must suffice for their colour description, as what is true of a cake is true of a column in THE GARDEN—you cannot eat it up and have it. Anthony Roozen, rose, edged blush; Bleu Amiable, a purple mauve; City of Haarlem, dull red; Clio, bisent colour; Gudin, mauve; Inglescombe Yellow, emary yellow; Jaune d'Œuf, yellow brown; King Harold, deep carmine; Morales,

plum purple; Painted Lady, almost white; Professor Rauwenhoff, rosy red; Suzon, pale pink; and William Pitt, blood red.

For Garden Decoration.—This list is not my own, but it is all the better for that. I asked my head-gardener to make a list of the thirty-six varieties that he considered were the most popular among our visitors this last spring. As I am away a good deal, he takes more round than I do, and I rather fancy he hears in plainer words than I do what they really think; hence its value. I am writing in the very early morning, and I have no idea what his list contains. I feel quite anxious for after-breakfast to come so that I can go out and get it. As he gives it to me, so will my readers have it, with no alteration and without any comment but this—that those varieties of which I have only a very few, such as Gertrude, Crepuscule and Royal Visit, are almost necessarily unnoticed by visitors who have only an hour or two to spend among the 500 or 600 kinds that I grow. In the list, again, the description will be an approach to the vanishing point. For convenience of reference I have roughly grouped them in colours.

Red and rose shades: Cassandra, rose; Emerald Gem, orange cherry; Isis, bright red; King Harold, dark crimson; Mrs. W. O. Wolseley, pointed crimson; Orange King, orange red; Pompadour, dwarf blood red; Prince of the Netherlands, deep rose; and Tara, deep ruby red. Yellows: Ellen Willmott, pointed pale lemon; Moonlight, long pale yellow; Solfatare, early, pointed pale lemon; and Walter T. Ware, deep golden yellow. Dark shades: Giant, dark reddish purple; Kingscourt, ruby violet; Velvet King, dark purple; and Zulu, darkest plum purple. Purple: The Bishop, real purple.

LILIAM BROWNII, A BEAUTIFUL SPECIES FOR THE OUTDOOR GARDEN OR GREENHOUSE.

Mauve: Melicette, lilac; and Salomon, pale rosy mauve. Brown shades: Clio, biscuit brown; Garibaldi, early, yellowy brown; Goldmine, orange and brown striped; Gondvink, tortoise-shell brown; Hammer Hales, pale copper, flushed orange red; Old Times, brown, edged buff; Quaintness, coppery orange; and Toison d'Or, deep orange and brown. Picotee: Carnation, white, edged rose. Pink shades: Clara Butt, pink, flushed salmon; The Fawn, palest fawn; and Suzon, warm flesh pink. Art shades: Le Rêve, pinky lavender; Beauty of Bath, pale lemon and palest mauve; and John Ruskin, rosy apricot. Slaty coloured: Norham Beauty.

A few remarks on the foregoing list may be of interest. Of all the 500 varieties which I grow, perhaps the most popular of all was Moonlight, and yet the Royal Horticultural Society's Tulip committee refused it an award. I can only say they cannot really know many of the flowers which they are called upon to judge, if they would pass this by.

My gardener found what I did. Quite four out of five visitors went for the "brownies." Clio and Gondvink were in big masses, and there was a good deal of Toison d'Or, but Quaintness in the list rather surprised me. Garibaldi was an outstanding tall early, and deserves wide recognition. Goldmine I like exceedingly, and I am glad to find others appreciate it. I have a large bed for next spring, for I have put all my little bits of it together and bought some more. No "broken" Tulip appeals to me quite like Goldmine. There is such a rich, good look about it, like a good bit of material.

Salomon is the most lovely of all rosy mauves or heliotropes. It is a Dutch breeder, very scarce, for I never meet with it, and not a very quick increaser. It has taken me a long time to work up enough stock to fill one of my 13-yards-long beds, but I have done it at last.

The superb Louis XIV. was next to Kingscourt. I do not at all agree with my visitors' choice, and I know one good friend, a Victoria Medallist of Honour with a double-barrelled name,

who will not either. I have just written a book on Tulips, and he wrote to implore me whatever I did not to leave out Louis XIV. As if I could! I have just looked up what I said, "a Tulip of exceptional magnificence." Kingscourt is, however, a very good flower.

Although I love the very dark shades, I know many do not, and I hardly expected to find Giant, Zulu and Velvet Gem put down. I suppose Giant impressed people by its height and size. We measured nearly every Tulip this year, and this and Viola were the only ones that touched 3 feet. The shade of Emerald Gem is unusual. I have come to like it very much. Most people "put it down." Now Baylor Hartland has gone it will have a sentimental interest added. He found it out and gave it to us, as he did a number of other good Tulips and Daffodils, and I wish that he still lived to give us more.

JOSEPH JACOB.

LILIUM BROWNII.

This beautiful Lily is worthy of more general cultivation, both for greenhouse decoration and outdoors, as, generally speaking, it is not a difficult Lily to cultivate. Naturally, it is best suited in a good medium loam, but, as in the case of the bulk of Liliums, it pays to prepare a special compost for them. This should consist of a rich light loam, with the addition of a little peat, plenty of leaf-soil and sharp silver sand. The proportions of the above will, of course, vary according to the class of loam one has to deal with.

In common with most Liliums, the best position outdoors for this handsome species is in a bed of dwarf-growing shrubs. Here the young growths are sheltered from cold, cutting winds during the spring. Another important point which is often overlooked is the fact that the roots of the shrubs help to keep the soil sweet and in good mechanical condition.

gives this Lily a very striking appearance. This brown colouring is, of course, much deeper outdoors than on plants cultivated under glass. There are several fine varieties of this Lily, such as Colchesteri, Chloraster and leucanthum, but at present they all seem scarce in cultivation. J. C.

JAPANESE ANEMONES IN THE WOODLAND.

For making an effective display in the open parts of the woodland during the early autumn months, few plants are better than the Japanese Windflower, *Anemone japonica*. Delighting as it does in a moderately rich, deeply-dug soil, where its long, thick roots can feed freely, it is essential that these conditions be afforded it. Grouped in front of coniferous or other dark-foliaged trees, as shown in the accompanying illustration, the beauty of the flowers is revealed to the fullest extent, and this is a point that should be fully borne in mind

AN EFFECTIVE GROUPING OF JAPANESE ANEMONES. NOTE THE DARK BACKGROUND OF TREES. NOW IS THE TIME TO PLANT!

The cultivation of this Lily in pots for greenhouse decoration presents no more difficulty than that of the more commonly grown *L. longiflorum*. As soon as received the bulbs should be potted up, putting three or four, according to size, into a 6-inch pot, or they may be potted singly into 4½-inch pots, using a light loam with the addition of a little peat, leaf-soil and sand. A little charcoal added will help to keep the whole sweet. After potting they should be stood in a cold frame until they have made plenty of roots, when they may be introduced to a warm greenhouse. They should not at any time be subjected to high temperatures, as they are best when allowed to come on gradually.

This Liliium generally grows from 2 feet to 4 feet high, and as a rule bears two or three flowers on a stem, which, when well grown, are as much as 9 inches in length. The inside of the flower is white, the outside a rich brownish purple, which

when planting this exquisite Windflower. Although it can be planted in early spring, many good growers prefer to plant it now, so that the roots get to some extent established before severe frosts are experienced. There are a number of varieties, but for woodland planting the type is admirably adapted.

SEASONABLE NOTES ON CARNATIONS.

Protecting from Sparrows.—The Carnation is beyond dispute one of the most useful of all the plants which can be persuaded to thrive satisfactorily in the restricted patches which are popularly dignified with the name of town gardens. The plants do not resent the lack of fresh air to any appreciable degree, and the fact that the soil is often extremely poor troubles them not at all. One would not dare to affirm that the blooms are quite as handsome in form, large in size, or

pure in colour as those produced by plants in country places; but they are really excellent and bring an infinite amount of pleasure to their owners. The plants are so accommodating that there is only one very real trouble, and even that does not occur in all gardens or in all districts. I refer to the partiality of sparrows for the leafage. In many gardens nothing short of a complete network of strong thread, repaired as necessary to maintain it in perfect condition, will keep a single sound leaf on a plant; while in other gardens, where the perky visitors appear to be equally as numerous, not a single plant will be touched. I do not pretend to know why this is so, but I strongly urge growers, on the first signs of attack, to net over and round each plant so efficiently that it is impossible for

that must be allocated to the task. It is essential that the cutting shall be extremely shallow, and, needless to say, roots must not be in any way disturbed or the growths injured.

Plants in pots in frames demand rational treatment. Carnations are hardy plants, except with some few tender varieties and in places where the soil and surroundings are peculiarly unfavourable. The trouble is, however, to persuade many amateurs to treat them as such. Because they are to be wintered in frames, they at once commence to keep the light close, neglect to admit fresh air, and the plants become weak owing to the unnatural manner in which they are being treated. Have nothing to do with any system like that. Never close the lights entirely, and whenever the external

Earl of Gosford (S. McGredy and Son, 1912).—To a certain extent the foregoing remarks apply equally to this Rose. Its colour alone will commend itself to exhibitors. It is a good dark crimson, very fragrant and an excellent grower; but the flowers are not more than medium size. It has done very well with me, and I have not seen a bad flower of it all the season.

Edward Mawley (S. McGredy and Son, 1912).—Be the reason what it may, this Rose has not been so fine with me as I should have liked, and I have not had such good flowers as one would reasonably expect from a Rose of its reputation. Whether the weather was too hot for it in the early season, or whether I failed to give the Rose the treatment it wished for, I cannot say, but I could not get the desired point or the size that I had the previous year. As seen at Portadown, all this was altered, and there was no difficulty in cutting and finding many fine flowers; but apparently it must be cut young and not allowed to develop too far. Its wonderful colour makes it an essential Rose to the exhibitor, but it requires the best of culture.

Elizabeth (B. R. Cant and Sons, 1911).—A pink Druschki is quite a fair description of this Rose. It is so free-flowering that it must be heavily disbudded to one bud. It has been very good with me—quite up to exhibition standard, and is catalogued at 1s. 6d. this year by the raisers, so should be tried if not already grown.

Evelyn Dautesey (S. McGredy and Son, 1911).—This is another good Rose from Portadown of the old Grand Duc de Luxembourg style of colour and strain, with the advantage that it is much finer in shape and holds up its flowers erect, which the old variety failed to do. Its

A BED OF ROSE LADY ASHTOWN, A BEAUTIFUL PINK VARIETY FOR MASSING. (See page 555.)

the birds to reach it as this is the only means of ensuring success.

Winter Treatment.—It cannot be urged against border Carnations, whether they are wintered in beds or borders, or in small pots in cold frames, that they make serious demands upon the time and skill of the cultivator; but there are necessarily certain things which will demand attention, and their neglect will have to be paid for in the form of inferior flowers the next season. In the case of outdoor plants—and this system of wintering is to be preferred where the soil is on the light side and the garden does not lie in a valley—it is imperative that their position in the ground shall be keenly watched, as frost is decidedly apt to lift them up, and to leave them thus is to court the disaster which will inevitably follow. Immediately such a state of affairs is seen to prevail, press the plant back into its correct place and make the soil as firm as, or rather firmer than, it was before. The trouble may, of course, recur, and therefore the look-out must be incessant. In no circumstances must weeds be permitted to grow in the beds or borders, and hoeing is the easiest method of keeping them in proper subjection. It is improbable that they will grow to any material degree, but hoeing will keep the surface open and thus encourage the unrestricted admission of fresh air, and should therefore be done regularly when the condition of the soil will admit of it, as the reward for the latter advantage alone is ample for the time

conditions will permit of it, admit all possible a.r. Torrential rains and snows must be excluded, and frost must not be permitted to freeze the soil to the point of breaking the pots; but except for these things, which have to be guarded against, Carnations must be kept as strong and hardy as possible through the winter to prevent worry and often great disappointment in the following spring and summer. F. R.

THE ROSE GARDEN.

NOTES ON NEWER ROSES. HYBRID TEAS.

(Continued from page 540).

Duchess of Westminster (Alex. Dickson and Sons, 1911).—This is one of those Roses that perform very much better than they promise. Judging from the buds, one hardly expects they will produce a perfect flower; but they do, and the resultant feeling of satisfaction is possibly all the greater. The colour is distinct clear rose madder pink. The blooms are of fair size, of good shape, unlike any other Rose in the shape of its petal, but none the less pleasing on that account. It is also sweetly scented, a good grower, and has good lasting powers when cut. Its only fault is that the flowers are not of the largest size compared with other Hybrid Teas, but some of us prefer beauty to weight.

colour is salmon, with the contrast of a deep carmine rose. It is very free-flowering and is naturally a garden Rose, but, disbudded, its fine shape will entitle it to a place among exhibition Roses.

Ethel Malcolm (S. McGredy and Son, 1910).—The more I see of this Rose the better I like it. It is flesh colour, with a blush centre, a description, perhaps, that hardly does it credit; but I consider it the best Rose of its colour. Fine foliage and a good grower, without being too vigorous; scented, so that it is difficult to find fault with it. Very early and very freely exhibited at the early shows. It is a Rose that always comes a good shape, with a beautiful guard petal and fine point, and generally of that useful kind which is so much wanted. It is bound to take a high place in Mr. Mawley's Analysis.

Ferniehurst (Alex. Dickson and Sons, 1911).—Not an easy Rose to describe as far as its colour goes—coppery pink on fawn the raisers call it. There is a suggestion of those sunset colours—the colours that have no name—about the flower that render it very charming. It is globular and imbricated in shape, with plenty of petals, and its growth leaves nothing to be desired. I had a glorious flower of it that I remember took Mr. Mawley's fancy very much. It has been consistently good with me, but as it requires time to perfect its flowers, they must be protected from rain.

George Dickson (Alex. Dickson and Sons, 1912).—"The Rose of the year" as far as exhibition Roses are concerned. No Rose has obtained so many silver medals as the best Hybrid Tea at so early a stage in its existence as George Dickson has to its credit. It was awarded the gold medal at the Ulverston Show in 1911. I remember at the "National" in July, 1912, my opinion was asked as to the respective merits of two Roses for the medal for the best Hybrid Tea in the show, and they were both George Dickson! I do not think it is any exaggeration to say that during the show season it secured a silver medal every week. It won a silver-gilt medal at Saltaire as the best Rose in the show, and followed it up by taking the Hybrid Tea medal at Belfast. Messrs. Alex. Dickson and Sons have sent out the finest exhibition Roses that we have, and they have no hesitation in describing it as the best exhibition Rose they have ever raised. I saw it growing at Newtownards, and the flowers were simply perfect. It is undoubtedly the best dark Hybrid Tea. The battle of the reds has waged long and furious. General Jacqueminot (1853), Charles Lefebvre (1861), Horace Vernet (1866), Duke of Edinburgh (1868), A. K. Williams (1877), Victor Hugo (1884), Ben Cant (1902), Hugh Dickson (1904), J. B. Clark (1905), Edward Mawley (1911), Leslie Holland (1911) and George Dickson (1912) each in its turn has been the "King of Roses"; but I think they and their respective champions (for each of the above Roses some exhibitor could be found who would be prepared to give his favourite variety his vote—I am backing George Dickson) will have to admit that a new king has arisen, and their favourite is deposed from the throne he has occupied. I am glad that at last a Rose has been found worthy to bear the name of "George Dickson"
Southampton. H. E. MOLYNEUX
 (To be continued.)

ROSE MME. JULES BOUCHE.

EXHIBITORS will find this to be a splendid acquisition. It has the grand high-centred form of Pharisæer, and even higher than that fine variety, but is also a much fuller Rose, and of a delicate ivory white colouring. It reminds one much of the old Souvenir d'Elise Vardon in its refined bloom. Although classed as a Hybrid Tea, there is much of the Tea nature in its growth; but it is quite erect in habit, so that it may also prove a most useful addition to garden Roses. Its fragrance is also very lovely.
 DANECROFT.

ROSE LADY ASHTOWN.

IN Lady Ashtown we have one of the best of Hybrid Teas for bedding purposes. It is good in all weathers, and as it opens well either in a cold wet summer or in a hot, dry one, it is obviously well adapted to the British climate. Moreover, its flowering season is extended over a long period, and even at the time of writing (October 24) it is making a brave show with its bright pink blooms in a Surrey garden. Unfortunately it is rather addicted to mildew, but it is such a good Rose in every other respect that we may well overlook this failing.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Continued from page 541.)

The Inexpensive Rockery.—The idea that a rock garden must of necessity be of a costly or elaborate nature may at once be dismissed as erroneous, since it is within the reach of all. It may, indeed, be either of a few yards in extent or a few acres, according to circumstances. It may be of towering character or only a foot or 2 feet raised above the ordinary level, or like that at Kew, which in part is below the ordinary level of the surrounding soil. Or it may be nothing more than a raised rockery border, that modified phase of the subject satisfying to many, and out of which much pleasure is often forthcoming. Be it large or small, dignified or unpretentious, one great principle must be kept in view from the start, viz., that to a number of alpine plants perfect drainage is of the highest importance. Hence in the case of the unpretentious structure or the rockery border a slight excavation of the ordinary soil might prove desirable, so that clinker, rubble, stone or the like may take its place, and thus ensure the more complete drainage one has in mind. To what extent this will be necessary will depend very much upon the nature of the subsoil, soils of a clay-like tenacity requiring to be moved to a few inches deep, while those of a light, sandy nature

hence the presence to-day of the rockery in small as well as in large gardens. Naturally, therefore, the selection of a suitable site in the case of the former borders on the grotesque, and suburban dwellers have to make the best of the circumstances over which they preside. Even to these a few hints, mostly of a negative kind, may not be out of place. For example, in not a few small gardens the ubiquitous Privet is almost sure to be found, and if its owner has not the heart—or shall I say the presence of mind?—to make a bonfire of it on Guy Fawkes Night, let him at least give it a wide berth in the matter under consideration. Then, again, corners should be avoided and the near presence of buildings or walls, unless the erection can be carried sufficiently high to obliterate to some extent such things, which is neither impossible nor impracticable.

In the larger garden this phase of the subject should receive more thought, and a rock garden in view in near proximity to the house where regularity of outline or formality prevail would be quite out of place. The immediate vicinity of trees is ever to be avoided, as much by reason of their root-spread as by the dangers arising from excessive drought, either from the presence of root-fibres or their overtopping branches. The continuous drip from trees, too, is highly dangerous—often fatal—to alpine vegetation, and the fact cannot be too loudly proclaimed. In this connection the operator would do well to keep in

A VIEW IN THE ROCK AND WATER GARDEN AT DRYNHAM, OATLANDS CHASE. (See page 56.)

may, in conjunction with brick rubble or old mortar, constitute a perfect rooting medium for the plants.

Suitable and Unsuitable Sites.—In the last issue some of the objects for the existence of a rock garden were considered in conjunction with that modified type which I designated "the unpretentious" to show that a rock garden need not of necessity be constructed on any elaborate plan. Coming nearer to the point at issue, one feels the need for keeping abreast of the times and for catering for that ever-increasing class who delight in cultivating the flowers of alpine regions;

mind the famous Friar Park example, for of the many object-lessons of which it is the demonstrator, this keeping of tree-life at a safe distance is assuredly one of the greatest. It will be noticed that the entire erection is open and exposed, admitting the fullest sunlight and air, in agreement with that greatest of all teachers—Nature—which it has endeavoured thus modestly to copy and imitate. It is this same principle, however, that I would like to impress upon all readers, since there is nothing of greater import at the outset.

For the rest, our rock garden may go almost anywhere we please, and seeing that so few gardens possess the natural advantages of rocky or undulating banks or surfaces, the majority are the result of adaptation to circumstances. In the matter of a site, that having a nearly or quite flat surface is among the most unsuitable, seeing that its natural advantages are nil, and that everything depends upon the skill, foresight and intelligence of the builder. Still, an interesting rock garden is not an impossible thing even amid such surroundings, as witness that at Kew, first carved out of a portion of an existing lawn. In this instance the rock garden in large degree exists in a depression of the ground, in which, however, much naturalness has been created from time to time. Then in the splendid example just completed at the Royal Horticultural Society's garden at Wisley we have the evidence the advantages a Nature-designed position affords, and which, in conjunction with a bold and successful treatment, will render it presently among the best of those available near London. These, then, are

Bays and prominences should likewise play their part, providing a greater variety of aspect on a minimum area of ground, the bolder rocks forming them meanwhile constituting sheltering glades at their bases, while affording a congenial home at their summit for trailing plants or the greatest of sun-loving subjects. E. H. JENKINS.

(To be continued.)

AN INTERESTING ROCK GARDEN.

THERE is a special feature of interest associated with the rock garden shown in the illustration on page 555, since it was originally constructed at the Royal International Horticultural Exhibition held at Chelsea in the spring of this year. It was there exhibited by Mr. Wood of Boston Spa, and the rock garden, as then shown, formed the subject of an illustration in our issue for June 8 (page 203). This well-arranged and compact rock garden was purchased by Mr. Arnold Weiss, who is evidently a good judge of a suitable home for alpine plants. This same rock garden now stands in the owner's garden at Drynham, Oatlands Chase, near

SPIRÆA DISCOLOR, A BEAUTIFUL SHRUBBY SPECIES THAT MAY BE PLANTED NOW.

varying types of the work, and are worth seeing and consulting by those having the construction of a rock garden in mind.

The Question of Form or Outline.—The first essential here is naturalness, and Nature, with all the object-lessons she reveals, must be kept in mind throughout. For example, on a mountain slope or hill there is no such thing as a straight line, and formality is non-existent. Nature has been its sculptor and fashioner for centuries; hence naturally, also, our imitation of such work will be as crude as it is feeble and incomplete. But even so we can at least mark and inwardly digest the principles which such work embodies, and in our imitations get as near the original as possible. In Nature, of course, we see more than one type; but it is the graceful outlines of our own hillsides, with their now rugged prominences or outcropping rocks, that possess the greater teaching value for the rock garden builder. Ruggedness and naturalness we may—must—have, and boldness, too, where circumstances permit

Weybridge, where it is well situated on the banks of a beautiful water garden.

TREES AND SHRUBS.

THE MYRTLE.

IT would seem to most people that there is little or nothing to be said about such a well-known plant as the Myrtle (*Myrtus communis*) more than has already been said. This is probably true, but well-known and interesting facts in connection with plants, as well as with other matters, are apt to be forgotten in the whirligig of time, especially when the object around which the interest centres is absent from thought or sight for some time.

Years ago the Myrtle used to be very much cherished in other counties than the West as a pot plant for the inside of a living-room window, not only for the beauty of its white star-like flowers, but also for the perfume emitted from them; but

in Devonshire there is no need to grow the plant indoors, for it flourishes so well in the open as to constitute it a common garden plant, either in bush or tree form, or for covering the front of many a cottage from the ground to the eaves of the thatched roofs, and more often than not with a thick woody stem, indicating that the plant is of some considerable age, the wood being very close-grained and extremely hard, but on account of its small size is used only for turnery purposes.

In any form the Myrtle is an object of beauty, the silvery white star-like flowers being set in a background of glossy green leaves; but it is a plant that would seem scarcely appropriate for a close-growing dwarf hedge, suitable to be clipped by the use of shears. Yet in a front villa garden at Exmouth a few days back I saw the plant so treated, and though the hedge was quite trim and neat, having apparently been recently cut, the flowers were peeping out all over it, giving to the whole a very attractive appearance, besides which the scent from the flowers must at times be very pronounced. It may be worth noting here that the flowers had at one time a commercial value for the production of an otto produced by distillation and used as a perfume.

The Myrtle may well be classed as an economic plant, for every part of it has at some time been put to some useful purpose. Thus, in India, where the plant forms a shrub indigenous in the area from the Mediterranean region to Afghanistan and Baluchistan, the bark and leaves are used for tanning, while an oil is obtained from the berries which is said to promote or strengthen the growth of the hair. Besides all these uses, the several parts of the plant are credited with medicinal properties; as, for instance, the leaves are used in India in epileptic cases, as well as in dyspepsia and diseases of the stomach and liver. Carminative properties are attributed to the fruits, which are administered in cases of diarrhoea and dysentery.

Though the common name, Myrtle, is well known in this part of the world as referring to *Myrtus communis*, in Australia it is applied to a large number of trees and shrubs belonging not only to the Natural Order Myrtaceæ, but to various other Orders. The most important, however, is that of *Fagus Cunninghamii*, a very large tree allied to our common Beech, but producing a beautifully-figured, dark reddish wood, much valued for furniture. J. R. J.

SPIRÆA DISCOLOR.

THIS is a useful shrubby Meadow-sweet grown in some gardens as *S. arifolia*, a name derived from the fact that the leaves resemble those of the White Beam. A native of North-Western America, it is an old garden shrub, though by no means a common one. Mature bushes are from 6 feet to 12 feet high, which at the end of June and during July produce a profusion of the many-flowered terminal panicles of creamy white blossoms. As may be readily observed by the illustration given on this page, *S. discolor* forms a large, graceful bush. No hard-and-fast rule of pruning is required, all that is necessary being to thin out the growths when becoming too thick by removing the old worn-out wood. Soil is not an important matter with this *Spiræa*, though good loam and an occasional dressing of manure are helpful. Propagation is effected by seeds and cuttings. The latter, made of the young, ripened wood about a foot long, may be inserted outside at the present time, or cuttings of half-ripened wood can be inserted under glass during August. A. O.

GARDENING FOR BEGINNERS.

PLANTING BULBS IN GRASS.

IN springtime bulbs are welcome whether grown in pots, borders, or grass plots. They are extremely beautiful in any position, and add very considerably to the attractiveness of the garden. If bulbs are planted under the turf where the soil is very poor, the growth will not be of great strength, and if the inexperienced cultivator unduly enriches such soil by adding rotted or other manures in bulk, the grass will grow very grossly in patches, and this will mar the general appearance of that part of the garden where the bulbs are planted. A soil of moderate richness does not need any manures added to it. Poor soils do, and the manure should be put in as follows: When the holes for the bulbs have been made, the soil immediately below the point where the bulbs will be placed must also be taken out and some well-rotted manure put in, not in large quantities, so that the growing bulbs will benefit and not the grass. Replace some of the soil and thoroughly mix it with the manure. If a small quantity of road scrapings, old potting soil, or any similar material which is procurable be put on the manure mixture, it will form a fit base for the bulbs.

Good Positions for Bulbs.—Nearly all kinds of bulbs that are usually grown in garden borders are suitable for planting in grass, the Hyacinth and Tulip not answering so well. Narcissi, Jonquils, Snowdrops, Crocuses, Scillas, the Grape Hyacinth and Ixias are very suitable. Under large trees with spreading branches, near hedges, in dells, in woodlands, on the lawn (in odd corners or at the edge of it) and on banks, bulbs look charming when in full flower.

Formal and Informal Planting.—When grown in the garden borders there must be a certain amount of formality in the arrangement, but when grown in grass the formality may be avoided. Informal

clumps are the most pleasing. My meaning will be made quite plain if readers will refer to No. 1 in Illustration A. The crosses there denote clumps of bulbs in the grass.

How to Plant Bulbs in Clumps.—No. 2 shows the turf turned back, and the circles in the soil beneath, indicated by No. 3, are the parts that must be broken up for the bulbs before the roll of turf is replaced. No. 4 shows a bank, the bulbs being planted in various positions on the bank itself, No. 5. The way in which the bulbs should be planted in clumps and singly is shown at Nos. 6 and 7, where turves are turned back for the purpose. Then there is a way of planting without

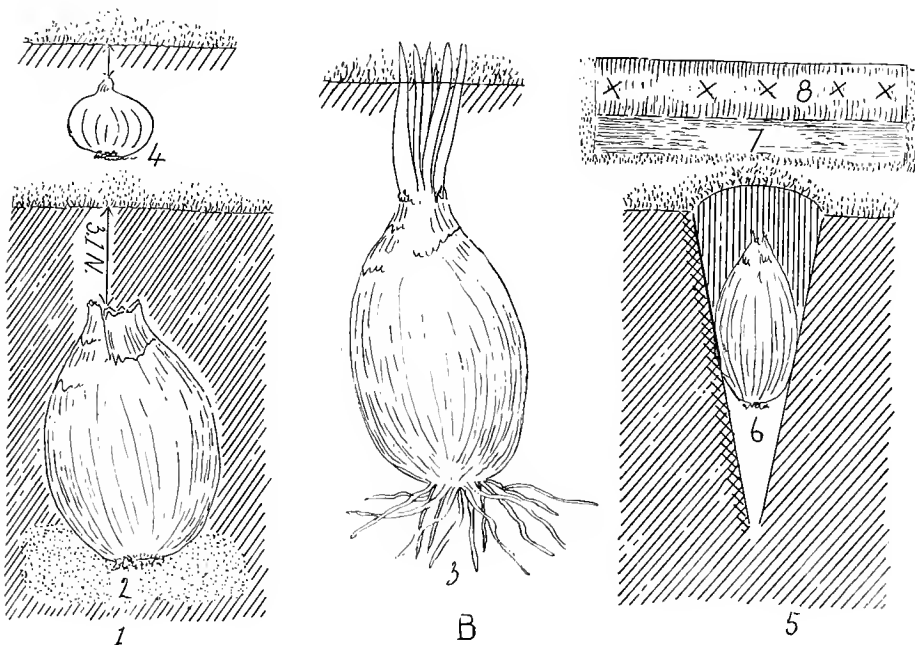

peeling off turf at all. It is shown at No. 8. The turf is simply cut crosswise and gently raised at the edges; then the soil is scooped out with the aid of a trowel, the soil is broken, the bulb planted and the turf firmly replaced.

In the Illustration B the method of planting is shown. No. 1, a Narcissus bulb planted 3 inches below the surface with sand or sandy material at its base, No. 2, to ensure a free root action. No. 3 depicts the same bulb making growth very early in the spring through the turf. No. 4 shows the comparative depth at which the smaller bulbs, *i.e.*, Crocuses and Snowdrops, should be planted. No. 5 denotes a section of soil in which a bulb, No. 6, has been wrongly planted. It is not right to simply make a wedge-shaped hole with a sharp instrument and then forcibly thrust in a bulb as indicated. Such bulbs will grow, but not very satisfactorily. No. 7 indicates the soil below the peeled-off turf. When the bulbs are planted in the soil, the roll of turf, No. 8, should be pierced in several places (as shown by the crosses) immediately above the positions; then the bulbs will grow through freely.

G. G.

METHOD OF PLANTING BULBS ON LAWNS AND GRASSY SLOPES.

RIGHT AND WRONG WAYS OF PLANTING BULBS.

CLEMATIS PANICULATA.

NATURALLY late in flowering in most seasons, the blossoms of this Clematis are spoiled by frost before reaching maturity. The best results have so far been obtained in the milder parts of the country, or when the plants are growing against a sunny south wall. Making very good growths during the summer, these usually finish well by carrying a profusion of terminal and axillary inflorescences. The hot summers of the United States are responsible for the great popularity of *C. paniculata* in that country, where it flowers annually in great profusion. The plants are very vigorous in growth, attaining a height of 20 feet to 30 feet or more. The pinnate leaves are dark green and shiny, the flowers white, 1 inch to 1½ inches across, with a sweet but not very strong fragrance. It is a native of China and Japan.

A. O.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Tulips.—To have satisfactory results, these bulbs should be planted without delay in a fairly rich, porous soil occupying an open, sunny position. When planting, bury the bulbs as near as possible the same depth; this will ensure their blooming all at the same time. Select varieties that are specially recommended for bedding purposes by the merchants, and plant one variety at a time so as to prevent any confusion of the sorts.

Planting Roses.—If the site is not ready for immediate planting when the plants arrive, they should be laid out of doors in a shallow trench with the roots well protected with soil, and, should the roots be dry, immerse them first in water and soak them before heeling in. Before planting, cut off any damaged roots or coarse ones devoid of fibre, using a sharp knife and always cutting from the under side towards one. Plant as near as possible to the same depth as before, always allowing for the plant to settle a little, and make firm by treading. Unsuitable soils may be improved by adding good turfy loam, cut from an old pasture, and farmyard manure at the time of digging or trenching.

The Rock Garden.

Pernettyas.—Where space permits of the inclusion of berried shrubs, none is more beautiful at the present time than *Pernettyas*, and their evergreen foliage is attractive at all times. A shady and fairly moist position suits them, with a peaty soil or one containing plenty of humus.

Cotoneaster humifusa.—Though fairly new to cultivation, this shrub has become very popular for the rock garden, and is now very pretty and doubly interesting with its scarlet berries. The plant is absolutely hardy, and quite unlike any of the others in commerce. For clothing a rock or pocket its evergreen, creeping foliage would be hard to beat.

The American Cranberry (*Oxycoccus macrocarpus*) is now quite an interesting lowly shrub with its crop of reddish fruits, which are large considering the size of the foliage. Choose a fairly damp soil and add a little peat.

The Hardy Fruit Garden.

Pruning.—Where a considerable quantity of fruit trees have to be pruned, I advise an early start with some of the trees that have shed their leaves. The work of pruning and nailing on a north wall is not very envious in cold weather. Morello Cherries are usually first in the list, and with these it is necessary to lay in plenty of young wood to ensure a heavy crop of fruit. The later trees of Sweet Cherries also may be planted in the same aspect. If due attention was paid to the pinching of the breast-wood, little pruning will be needed. Lay in securely the growths that were left for extension, remove any dead growths or weakly shoots, but do as little pruning as possible, which is conducive to gumming and canker.

Plants Under Glass.

Palms.—At this season especially the pots are well filled with roots, and, in addition to manurial stimulants, a little soot-water will be valuable and materially help in keeping the foliage a good colour. The plants will not need shade any longer, and on warm, bright days keep them well syringed. Scale is one of the worst pests, and must be got rid of by sponging with an insecticide and carefully removing with a brush. Handle the plants so as not to injure the leaves, remembering that these should prove a source of attraction over a long period. Syringe afterwards with clean, tepid water.

Achimenes.—While the growth is dormant keep the pots or baskets of soil containing the corns in a warm place, and withhold water until re-planting again. If placed under a stage, lay the pots on their sides.

Caladiums.—To preserve these successfully during the winter months, the pots containing the tubers must be rested in a warm house, and, like the foregoing, when the foliage has ripened, be kept thoroughly dry.

Cyclamen.—These will now be past throwing up their flowers, and the plants will still benefit by occasional waterings with an approved fertiliser. We find Peruvian Guano, in addition to others, a valuable plant stimulant. Great care should be exercised in watering now, and avoid pouring the water on to the crown of the plant. Look the plants over occasionally and pull out any leaves that are decaying. Seedlings that were sown at a good distance apart in the pan will not need disturbing too soon, but any that are becoming crowded should be transferred to a pan or box or potted into small receptacles.

The Lawns.

Leaves.—Continue to sweep these up and cart away as often as possible. Though this seems labour in vain, it is highly beneficial to the grass, these frequent brushings distributing worm-casts. If allowed to remain, the leaves soon commence to rot, and are then very difficult to remove.

Pampas Grass.—This is extremely ornamental, and probably at this season one can locate the place where a clump or two would be a valuable improvement to the surroundings. The plants like a good soil, and are best planted or divided in the spring, when a fair-sized hole should be taken out and some better material added.

Fruits Under Glass.

Early Vines.—The earliest-forced Vines will now be ready for pruning and cleansing preparatory to being forced for another season's crop. The borders should have the surface soil and rubbish scraped off and taken away. How much may be removed depends upon the number of roots on the surface, which must be carefully preserved. Top-dress with some chopped loam to which has been added some lime-rubble, wood-ash and manure. Old turves laid downwards on a sprinkling of bone-dust and artificial manure make an excellent rooting medium. Give an abundance of ventilation whenever possible.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting.—Press to a conclusion the planting of border plants, bulbs for spring flowering, Wall-flowers, *Myosotis* and other plants for a similar purpose.

Roses.—Of these, home grown and propagated plants should be first transplanted, nursery plants not always being matured as yet, and having the foliage intact. In some instances it is good policy to lift and replant established Roses after thoroughly cultivating the soil and adding to it such manure as may seem fit. Scotch, Boursault, Gallica, Austrian Briar and other Roses that bloom early may be pruned now, or, rather, thinned of old and weakly growths.

Cultivating Flower-beds.—This is a suitable time to thoroughly cultivate the soil in beds and borders that have been occupied by summer-flowering plants. The soil is all the better if turned up annually to a depth of 18 inches, and a moderate amount of perfectly-rotted manure worked in. All flower-beds get out of shape, and the opportunity may now be taken to restore them to their original lines. It may be noted that beds to be occupied by *Begonias*, *Pentstemons*, *Antirrhinums* and other soil-exhausting plants may have a thin layer of manure spread over the surface. Soot is also helpful and, with the manure, becomes well mixed with the soil by springtime.

Storing Roots.—Great losses are frequently experienced with *Dahlias*, *Lobelia cardinalis* and others. *Dahlias* require a mild temperature of 45° to 50° to preserve the tubers, rot being almost certain to destroy them if too cold. They must be kept dry. *Lobelia*, on the other hand, so long as frost is not severe, may be frozen without harm. I keep them in boxes covered with leaf-soil in cold frames, and seldom lose any. *Begonias* are wintered in the Apple-room, laid out on the floor under the shelves. *Salvia patens* keeps best if buried deep enough to be out of reach of frost.

Shrubs.

Trimming.—Deciduous climbers, such as *Polygonum baldschuanicum*, now that they are denuded of foliage, should be roughly trimmed, and will be neater and less unsightly during the winter than if left to mature.

Protecting.—In the colder localities shrubs asking for protection during winter may now be seen to. Small plants are efficiently protected by means of very rough and loosely-made straw ropes wound around them. Very large ones may have straw or Bracken packed about the stems, and standard Roses and others should have Wheat or Rye straw placed lengthwise round the stems and tied top and bottom, and the straw near the top thickened to take in the heads. Spruce branches are usually employed to protect wall shrubs. They do not keep out frost; much as protect the plants from frost and thaw and the too rapid change brought about by the sun after hard frost.

Pruning.—In extensive shrubberies there is always a certain amount of dead wood to be expected annually, and previous to the general cleaning up before winter, an opportunity to cut it out may be taken. As little as possible of the dead material should be left. Dead portions, however small, have a distinctly injurious effect on ligneous vegetation, apart altogether from its unsightliness.

The Plant-Houses.

Roman Hyacinths.—These will now force successfully, the secret of success being to keep them darkened till the spikes are well advanced, after which a few days' exposure brings colour into the leaves and spikes. Too much heat is injurious.

Lily of the Valley.—Current year's growths may now be used. A strong bottom-heat with much moisture and darkness is essential, and only the best crowns should be used. A check is almost sure to prove fatal.

Perpetual Carnations.—Cuttings inserted three weeks ago will now be rooted, and should either be potted into 2½-inch pots if in boxes, or, if struck in 2½-inch pots, these should be removed to a cooler structure for a few days before re-potting.

Asters.—Climax is a delightful plant for the conservatory. Single growths rooted in spring, planted out, and lifted not long ago and potted, are of much value for greenhouse decoration and cut flowers now and later. Jessie Croom is also useful, and other late sorts may be treated in the same way, but Climax is certainly superior to any.

The Rock Garden.

Rearrangements.—Since last writing, part of the rockery here has been completely overhauled and rearranged, a nasty stoloniferous weed having got among the plants necessitating the operation. *Rose Hiawatha*, the newer *Deutzias*, *Astilbes* and other plants have been introduced, as well as *Iris*es, *Brodiaeas* and autumn-flowering *Crocuses*. Nowadays one must look to effect in all things, even in an assemblage of stones!

Cleaning.—Now that the foliage is off the trees, the rockery should be thoroughly cleaned of sticks, leaves and weeds, and any plant needing protection seen to. Some nice fresh compost neatly scattered over bare surfaces adds to the general appearance and gives it a cared-for aspect. Where slugs are troublesome, dustings of soot are of value, and they are also effective manurially to spring bulbs. *Colchicums* and autumnal *Crocuses*, which are all making roots.

Hardy Fruit.

Gathering.—The weather must be closely watched, so that the latest Apples and Pears are not caught by a severe frost. Generally the week we are entering on is quite late enough to let them hang. If the fruit cannot be gathered perfectly dry, see that it is dry before storing.

Planting.—Young trees from Southern nurseries are, as a rule, ready to plant about this time. From Northern nurseries it is better to delay two or three weeks before having them sent on. The chief point to observe in planting is the trimming of the roots, especially the broken and extra strong ones, planting just deep enough and giving efficient support to the trees till established. Early planting conduces to immediate root-production, and wind loosens and damages the new roots if the trees are unsupported. R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Scolopendrium vulgare crispum nobile (Bolton's Broad Form).—This is the somewhat cumbrous title of much the largest variety of Hart's-tongue Fern we have seen—large indeed even unto coarseness. Some of the biggest fronds measured 2 feet in length by 6 inches in width, the former taken from the soil to their tips; hence it is a giant in its tribe, and one in all probability whose present huge proportions do not represent full development. The coarsely cristate or fimbriate margins of the fronds present a plumose character generally, are of dark green colour, and are rendered the more attractive by reason of the almost ebony-coloured stem. The variety was first found as a wilding on Walton Crag, Lancashire. Exhibited by Mr. W. B. Cranfield, Enfield.

AWARDS OF MERIT.

Nephrolepis Millsii.—A distinct and rather neat-habited plant, the brownish-looking fronds of an acuminate character, and not unlike in form and colouring those of some of the *Polystichum aculeatum*s, though more erect. It increases freely by stolons and division, after the manner of its tribe. From Mr. W. A. Manda, St. Albans.

Chrysanthemum Mrs. John Maher.—A decorative Japanese variety of the purest whiteness, which is said to be a splendid keeper. Its purity alone will command for it a place, while its graceful and decorative character will assuredly please all. From Mr. T. Page, Hampton-on-Thames.

Chrysanthemum Mrs. Loo Thomson.—The shortest description of this excellent variety should also prove the most graphic, viz., that it is a sport from the beautiful single-flowered variety *Mensa*, sent out about three years ago. The colour is pale or canary yellow.

Chrysanthemum Charles Kingsley.—A single-flowered variety of a rich, almost intense golden yellow colour. It is one of those which impel admiration at a glance, at once of high decorative value and much excellence. These were exhibited by Mr. Norman Davis, Framfield.

Chrysanthemum Honourable Mrs. John Ward. A very large and handsome-looking yellow-flowered variety of the exhibition order, the long, drooping florets affording great depth to the flower-head as a whole. Exhibited by Mr. Charles Beckett, Chilton Gardens, Hungerford.

Chrysanthemum Boh Pulling.—A monster exhibition variety of good contour and form, and of intense golden yellow colour. The florets are of the drooping order, giving the flower-head great depth and importance, its value being enhanced by the exceptional richness of its colouring. Shown by Messrs. H. J. Jones, Limited, Lewisham, S.E.

Chrysanthemum J. W. Streeter.—A soft-coloured or canary yellow sport from the well-known and highly-popular Japanese incurved variety *H. W. Thorpe*, and, like the original, of excellent form and outline. We regard it as indispensable, albeit the rather formal character of these incurved varieties does not appeal to all. From Messrs. Cragg, Harrison and Cragg, Heston, Middlesex.

Chrysanthemum Miss M. Borrer.—An attractive single-flowered variety whose florets are coloured a deep rosy lilac. The colour is warm-looking, and should prove effective under artificial light. The naturally-grown sprays demonstrated

freedom and utility. Exhibited by Mr. L. F. Harrison, Orchards, East Grinstead. The stock is in the hands of Messrs. Whitelegg and Page, Chislehurst.

NEW ORCHIDS.

There were no fewer than ten new Orchids to gain awards; of them four received first-class certificates, and the remaining six awards of merit.

First-class certificates were awarded to *Cattleya labiata* Opal, a handsome white variety with a tint of pink and gold on the lip; *Brasso-Cattleya dighiano-Mossia* The Dell variety, a remarkably well-formed white variety raised by crossing *Brassavola digbyana* and *Cattleya Mossia* Wageri, both of the foregoing novelties being shown by Baron Bruno Schröder; *Cypripedium Pallas-Athene*, a flower of perfect shape, with dark purple spotting, shown by W. R. Lee, Esq., Heywood; and *Cymbidium Doris*, an interesting hybrid between *C. tracyanum* and *C. insigne*, shown by Messrs. J. and A. McBean.

Awards of merit were granted to the following: *Sophræo-Lælio-Cattleya Sandhage*, from E. H. Davidson, Esq.; *S.-L.-C. Menippe* H. S. Goodson, from H. S. Goodson, Esq.; *Lælio-Cattleya de Hemptinne*, sent by Count Joseph de Hemptinne of St. Dennis, Ghent; *Cattleya Princess Mary*, a hybrid from C. dowiana, shown by Pantia Ralli, Esq.; *Cattleya Maggie Raphael* Goodson's variety, from H. S. Goodson, Esq.; and *Lælio-Cattleya Golden Oriole* Holford's variety, exhibited by Lieutenant-Colonel Sir George Holford, K.C.V.O.

The foregoing awards were made by the Royal Horticultural Society at the meeting held on October 22.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

DAFFODILS FOR BEDDING (S. C. R.).—You cannot do better than employ such as *Emperor*, *Sir Watkin*, *Barri* conspicuous, *Grande*, *Poeticus* *Almira*, *Mme. de Graaff*, *Mme. Plomp* and *Empress*, all excellent and cheap sorts for the purpose named. You might plant the varieties at their own depth asunder, or twice that distance or even more, according to circumstances.

YUCCA FILAMENTOSA (M. A. R. G.).—The young growths which push up after a plant has flowered must be divided up singly. This may be done by taking them off and inserting as cuttings when large enough; or, if growing from the ground, divide them up when well rooted. May is the best month to transplant *Yuccas*. The cuttings will root best in a heated greenhouse.

NAMES OF CHRYSANTHEMUMS (A. E. H.).—We have experienced considerable difficulty in naming the blooms sent to us, as in almost every instance the numbers attached to them had become loosened in the course of transit through the post. We therefore give you the names as far as we are able to identify the colours and form of each one. They are as follows: *White Points* (rosy purple with white points), *Mme. Casimir-Perier* (white, freely suffused pink), *Crimson Marie Massé*

(chestnut bronze), *Horace Martin* (yellow), *Robbie Burns* (cerise pink), *Mme. Marie Massé* (lilac mauve) and *Ethel Blades* (compact crimson flower).

BANANA FRUITING OUTSIDE (T. J. S., Orled).—We are very interested to hear of your success in growing a plant of *Musa* (Banana) to the fruiting stage out of doors in this country. Your garden must be favourably situated for such a plant to grow outside for five years and reach a height of 8 feet. Plants of *Musa* fruiting outside in this country are occasionally met with, but it is usually in a sheltered garden in the South or West, Cornwall or Devon, for instance. There are one or two records of plants living outside in sheltered Surrey gardens. At *Coombe Wood* the Japanese Banana (*Musa Basjoo*) survived for several years. Coming from Japan, this is the name we should suggest for your plant. The fruits of this are about four inches long.

IRIS SUSIANA (A. F.).—This weird and beautiful *Iris* is only a success when given a special course of treatment, and is in no sense to be regarded as a reliable border plant permanently in this country. Native of Asia Minor and ripening early in the season, the plant usually receives a good ripening, which in the open air in this country is very rarely imitated. In the first year following importation the plants flower with a fair degree of certainty, as do others grown specially in such places as Guernsey. To succeed with it at all, it is best to regard it as a greenhouse plant, and, having flowered it, to place the pot or pan on a shelf where it will get the full benefit of the sun for three or four months, or even longer, no water being afforded meanwhile. The plants should not, of course, be so dried off until the foliage shows signs of maturing, after which, during the resting period, the plants should be kept absolutely without water. When restarting them into growth—they will do this naturally in December or thereabouts—meagre supplies of water should be given, and more as the leaf-growth advances. Kept in the fullest light and free from insect pests, flowering is more reliable, and the plants will not require potting more than once every two years. A marly loam, or one of good fibrous character with which old mortar rubble has been freely incorporated, will, with firm potting and perfectly free drainage, be all that is necessary from this point of view. We should advise you to start afresh with the best roots you can obtain.

EXHIBITING "HARDY PERENNIALS" (J. A. M.).—Unless the terms of the schedule contain some saving clause, the inclusion of *Dahlias* in an exhibit of "hardy perennials" should have been followed by disqualification, while the *Chrysanthemums* named would have given rise to serious doubt. In your favoured district the latter might come within the wording of the schedule, though generally for exhibition work it would not pass muster. The *Dahlia*, however, is another matter altogether, and even though the tubers of some varieties are hardy enough to endure if deeply planted and protected, the majority would not be so, and the plant would certainly not be; hence its inclusion would not be tolerated by 1 per cent. of capable judges. The case to which you refer, however, is the outcome of an ambiguous wording of the schedule, and a class for "hardy perennials" without any qualifying clause might include *Roses* and other flowering shrubs—anything, indeed, that is characterised by hardiness and a perennial duration. This looseness in the compilation of schedules is a pitfall to many, and the more confusing to exhibitors when the judging is not in competent hands. The secretary, in informing you that the *Dahlia* is a "hardy perennial," was obviously in error, as the first frosts of autumn should unmistakably prove. There is so much looseness of wording existing in schedules to-day that we hope to devote an article to the subject at a later date in the hope of making the way more plain to secretaries, committees and exhibitors alike.

TREES AND SHRUBS.

HORSE CHESTNUT LEAVES (Courtoun).—There seems to be no reason to doubt that the leaves you enclose are those of the common *Horse Chestnut*; but to make quite sure a flowering shoot is necessary. The colour of the leaves is both curious and interesting. It is probably one of two things—either a sport, or a portion of the tree unhealthy from disease. If you ascertain that the coloured leaves are not due to the second reason, then it is worth propagating by grafting on young plants of the common *Horse Chestnut*. Some of our most ornamental trees have originated in the first instance from sports. It might be worth while consulting a local nurseryman with a view to propagating ten or twenty plants, and watching their behaviour for the next two or three years.

THE GREENHOUSE.

SEEDLING FUCHSIAS (G. G.).—The expanded flowers on some of the specimens sent had dropped: hence it was difficult to make out to which number they belonged. They comprise a very pretty selection of seedling varieties belonging to that race we received from Germany a few years ago. Nos. 1, 3, 4 and 5 appear to us very much alike, and the best of the four should certainly be well worth propagating. There may be individual differences, but from the small sprays, with most of the expanded blooms fallen, one cannot say. No. 2 strikes us as a fine and, as far as we know, a distinct variety. It would be as well to submit them to some firm who make a speciality of this class of plants. At all events, we think, if you have a good specimen or specimens of the most distinct sorts, it would be a desirable plan to submit them to the floral committee of the Royal Horticultural Society, Vincent Square, Westminster, S.W.

DOUBLE BEGONIAS DROPPING FLOWER-BUDS (H. C.).—It is exceedingly difficult to answer your question, for though everything points to an error in culture somewhere, yet the details as given by you are such as should ensure success. The pots used are certainly rather small, and we are inclined to think that possibly the ball of earth gets too dry, an opinion strengthened by the fact that most of the blossoms drop directly they are watered. A reasonable amount of air should, of course, be given to the plants; while by the term "well shaded" we presume you do not imply that they are deprived of the very necessary light, but only protected from the sun's rays. We regret that it is impossible for us to put our finger on the cause of the trouble, but hope that our suggestions may help you to overcome it.

BEGONIA (W. T. E.).—Your Begonias are badly attacked by the Begonia mite, which seems to get more troublesome year by year. Last season the hot weather was blamed for its rapid increase, but it scarcely applies this summer, although the pest is as bad as ever. Not only are Begonias attacked by it, but many other plants. We have had, during the present year, several badly-infested specimens of Cyclamen submitted to us. The best way to get rid of the enemy is to dip the plants in a nicotine mixture, or to vaporise with the XL All Vaporiser. A single application will not, however, suffice, so it must be done three or four times at intervals of five or six days. A prominent feature of this pest is that it does such a deal of mischief before its presence is suspected; hence, though you may destroy the mite, you can never hope to restore the plants to their normal health this season.

FRUIT GARDEN.

PLANTING APPLE TREES IN ASPARAGUS-BEDS (J. D. B., Cambridge).—We do not advise you to plant Apple trees in the Asparagus-beds. They would, as you suggest, make very rank growth, and the Asparagus would also suffer.

LEAVES FOR INSPECTION (W. H. B.).—It is too late to do much now. The leaves have apparently been attacked by aphides in the early part of the year. Quassia and soft soap is the best spray to use, or a nicotine preparation, but it must be used as soon as the aphids hatch out in the spring, usually about the beginning or middle of April, if the spraying is to do its work properly. The Apple is Worcester Pearmain.

STORING WALNUTS (Hetty).—Walnuts when freshly gathered should be spread out in the sun either in an airy structure or out of doors for a few days to dry. They may then be packed in layers in jars or large flower-pots, with a little salt between each layer, and be buried in a heap of sand until required for use. Another way is to subject the Nuts to sulphur fumes for an hour or two, and then pack them in jars in the same way, afterwards burying the jars in sand. The sulphur fumes have the effect of killing any fungus germs which may be present on the shells.

LEAF-CURL IN PEACH LEAVES (J. R. K.).—It is cold weather which brings this about, this condition favouring an attack by a fungoid disease, which causes the peculiar distortions in the leaves. The best course to take in the matter is to pull off the diseased leaves and burn them. This will get rid of the green or black fly as well, which are generally found in the curled-up leaves. Other healthy leaves will follow. Messrs. G. Bunyard and Co., Limited, of The Nurseries, Maidstone, claim to have an effective preventive against its attack, provided it is applied when and as directed by them. It is called "Medela." Nothing can cure the leaves once they are affected.

TO GROW PEACH TREES IN POTS (J. C. Le S.).—The starting of these young trees by budding or grafting in the first instance, and the subsequent treatment of them, is no doubt interesting work; but it is of so highly technical a nature that an amateur without previous experience in the work would inevitably come to grief in the attempt and his labour prove abortive. It would be far better for you to purchase the young trees you may require ready grafted and ready trained. Two year old trees are to be obtained at little cost from any nurseryman advertising with us. The best time to purchase is early in November, when they may be top-dressed with soil, and the pots buried in fine coal-ashes to the depth of 4 inches above the pots in an open sheltered position. They may remain here until the time comes for them to be placed in the greenhouse, which should be the first week in February. Should frost prove severe during winter, the trees should have slight protection by having straw or bracken or mats placed round them. When taken into the greenhouse, give them the lightest and most airy position possible. The question of ventilation of the house and watering the trees is one of the most important items in the culture of these trees. There should always be a slight circulation of air round the trees, and they should never suffer from dryness at the root. On the other hand, it is equally important for them not to be too wet at the root for any length of time.

KITCHEN GARDEN.

CARROTS IN A WOODY CONDITION (H.).—Generally speaking, the cause of Carrots being in the condition you mention is poverty or shallowness of the soil or want of deep cultivation. Carrots grow best on land which has been deeply trenched and liberally manured for a crop the previous year. If you have not such a piece of land available, you should trench a piece as soon as you can (2 feet deep) or lay a good dressing of manure in the bottom trench.

MISCELLANEOUS.

MAKING A MORAINÉ GARDEN (J. B. C.).—An illustrated article on this subject appeared in our issue dated January 27, 1902.

MOLES UNDER PEAR TREE (O. H. B.).—We know of no method by which you can poison or suffocate the moles as you suggest. The only remedy seems to be to trap them by the usual iron traps. If you can find a run where they go to drink, this is the best place to set the trap, preferably in the hardest soil you can find.

VARIOUS QUESTIONS (E. J., Radlett).—Basic slag may with advantage be applied in the previous autumn to the ground destined for the Tomato. The phosphates will then be available for the crop. But why not lime the soil and then use superphosphate? The Apple marked (b) is the Siberian Crab. We regret we cannot name Apples from imperfect fruits. Typical ripe fruits should always be sent. The fruit is very badly attacked by *Fusicladium dentriticum*. Bordeaux mixture is the best thing to apply; but it is equally important to prune out all diseased shoots during winter, and to spray during winter with a solution of copper sulphate, 1oz. to twenty-five gallons of water.

BERBERIS BERRIES (J. F.).—The berries of *Berberis Darwinii* may be used in the same way as the common *Berberis* (*B. vulgaris*) for making into jelly, although they are not often used for the purpose in this country. *Berberis* berries are said to make an excellent preserve; but as the seeds are rather large, the boiled fruit requires straining and the juice boiling again before bottling. If you follow the method usually adopted for making Red Currant jelly, the preserve ought to be a success. There will probably, however, be a little more sugar required than is usual with Red Currants. In America the fruits of *Berberis Aquifolium* are used rather extensively under the name of Oregon Grapes. Certain Himalayan *Berberis* are also esteemed on account of their fruits. We have not heard of the fruits being used with whisky.

NAMES OF FRUIT.—*North Wales*.—Apple Northern Greening;—*Phœnix*.—2, Lamb Abbey Pearmain; 3, Dutch Mignonne; 4, Cellini Pippin.—*J. E. Phillips*.—1, Marie Louise d'Uccle; 2, Beurré Clairgean; 3, St. Luke; 4, Beurré Hardy; 5, Beurré Diel; 6, Beurré Dumont.—*Devonia*.—Margil.—*H. M.*—1, Stubbard; 2, Reinette Grise; 3, Wellington; 4, Lane's Prince Albert; 5, Braddick's Nonpareil; 6, Miller's Seedling; 7, Ribston Pippin; 8, Kentish Fillbasket.—*R. S. Wallins*.—1 and 2, Newton Wonder; Pear, Black Pear of Worcester.

NAMES OF PLANTS.—*E. H. L., Newmarket*.—*Rhamnus cathartica* (Buckthorn).—*R. T., Breconshire*.—*Juniperus Sabina prostrata*, or *Prostrate Savin*.—*S. P. R., S.W.*—1, *Chrysanthemum Rubis*; 2, *Seedling Chrysanthemum*; 3, *Sedum Anacampseros*; 4, *Sedum Sieboldii*.—*B. G.*—*Chrysanthemums*: 1, *Rubis*; 2, *Goacher's Crimson*; 3, *C. indicum flore plena*, *Asters*: 4, *A. multiflorus*; 5, *A. Amellus* var. *bessarabicus*; 6, *A. Novi-Belgii deous*; 7, *A. Amellus* variety; 8, *Sedum spectabile*; 9, *Stachys lanata*; 10, *Pulmonaria officinalis*.

SOCIETIES.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.

This society held its monthly exhibition in the Corn Exchange, Leeds, on October 17 and 18, when a fine display of fruit, flowers and vegetables was staged. The proceeds were given to the Leeds Workpeople's Hospital Fund. An eighty-guinea challenge cup for the best exhibit went to Mr. J. Pickersgill, Westwood, Leeds, for a group of foliage plants, consisting of well-grown and highly coloured *Crotons*, interspersed with *Ocimum* and *Cattleyas*. This group also secured the society's gold medal. Mr. W. D. Cliffe of Meanwood Towers, Leeds, took the fifteen-guinea cup for the best amateur exhibit, which comprised seventy-five dishes of magnificently grown vegetables. Mr. William E. Sands, Hillsborough, of Irish fame, had a large and interesting stand of sixty kinds of seedling Potatoes. The exhibit of Messrs. Webb of Stonbridge, containing fifty varieties of Onions, all well grown and admirably staged, came in for much attention from the visitors during the two days.

ORCHID COMMITTEE.

Messrs. Mansell and Hatcher, Rawdon, Leeds, had a most beautiful and tastefully-arranged group of Orchids. Every plant was a perfect specimen of culture, and this, combined with the arranging, left a deep impression upon those who had the pleasure of seeing it, the colours being so harmoniously blended that a fitting description can only be conveyed when describing it as a "harmony of mauves." The society's gold medal was awarded.

A silver-gilt medal was awarded to Mr. W. H. St. Quintin, Scampston Hall (gardener, Mr. F. C. Puddle), for a small group of seedling *Cattleyas*. Among them *The Bride* was awarded a first-class diploma, while *Lælio-Cattleya scampstonensis* secured a second-class diploma. J. H. Craven, Esq., The Beeches, Keighley, had many notable kinds in his collection. *Cypripedium Boltonia* secured a first-class diploma. Large silver medal.

Mr. W. Shackleton, Bradford, secured a bronze medal for a group, also a second-class diploma for *Cypripedium Charlesworthii*.

FLORAL COMMITTEE.

A group of foliage and flowering plants was exhibited by Mr. J. Pickersgill, Borden Hill, Leeds (gardener, Mr. J. Donoghue). Gold medal and challenge cup.

Mr. B. Bagshaw, Chapel Allerton, Leeds, showed *Carnations*. Bronze medal.

Messrs. William Cutbush and Sons exhibited *Michaelmas Daisies*, with *ericoides* predominating. Large bronze medal.

A large bronze medal was awarded to Messrs. Little and Ballantyne, Carlisle, for *Potatoes* and *coniferae*. Mr. T. C. Edwards, Leeds, showed a stand of hardy *Chrysanthemums*. Bronze medal.

Mr. A. C. Watson, Morley, exhibited *Begonias* of the *Gloire de Lorraine* type. Bronze medal.

For a collection of *Michaelmas Daisies*, Messrs. Harkness and Sons, Bedale, were awarded a bronze medal. This firm also received an award of a second-class diploma for a sport from *Chrysanthemum Goacher's Crimson* named Mrs. J. Fielding.

Messrs. S. Broadhead and Sons, Huddersfield, showed rockwork. Large bronze medal.

A silver medal was awarded to Messrs. Young and Co., Cheltenham, for a stand of bright and well-grown flowers. Among them were *Enchantress*, *J. Whitecomb Riley* and *Britannia*, which were very good.

Messrs. G. Gibson and Co., Bedale, were awarded a bronze medal for rockwork, also a second-class diploma for *Berberis Wilsonae*.

A large bronze medal was awarded to Messrs. William Bousall and Son, Harrogate, for an extremely fine collection of *Bouvardias* in many varieties.

For a stand of Apples, Pears and *Carnations*, Mr. William Laureuson, Yarn-on-Tees, was awarded a large bronze medal.

Mr. T. Blackburn, Huddersfield, secured a silver medal for a small group of well-grown *Carnations*. The individual flowers in this collection showed a high standard of cultivation. *Empress Day*, *Colossus* and *White Perfection* were outstanding among the many varieties staged.

Messrs. W. and J. Brown of Peterborough again had one of their attractive stands of *Roses*, the arrangement being excellent. *Mme. Victor Verdier*, *Juliet* and *Earl of Warwick* were good flowers for the time of the year. Large silver medal.

Messrs. John Hill and Sons, Stone, Staffs, were awarded a large silver medal for shrubs.

Messrs. Dickson and Robinson, Manchester, got together a very large group of *Chrysanthemums* and *Asters*, the most striking feature to be observed being the freshness and cleanliness of both flowers and foliage. We noticed such good kinds as *Mr. Cecil Davis*, *Ella*, *Ringdove*, *Albus*, *Climax* (very good), *St. Egwin* and *Thonsonii*. Large silver-gilt medal.

Messrs. Little and Ballantyne, Carlisle, were awarded a silver medal for shrubs.

A large silver medal was awarded to Messrs. William Wells, Merstham, Surrey, for *Chrysanthemums*, *John Edwards*, Cranford Yellow and *Miss M. Walker* being very good.

A silver medal was awarded to Mr. J. C. Fordy, Castleford House, Northumberland, for *Gladoli*.

A large bronze medal was awarded to Messrs. Ker and Son, Liverpool, for a stand of *Crotons* and *Cyclamen*.

A vote of thanks was given to the Lakeland Nurseries, Windermere, for an exhibit of *Begonias* and *Ferns*.

FRUIT AND VEGETABLES.

Mr. W. D. Cliffe, Meanwood Towers, Leeds (gardener, Mr. W. Haigh), was awarded a large silver medal and challenge cup for vegetables, *Onions Premier* and *Barnet Hero* being well grown. The collection of *Potatoes* was very creditable.

Mrs. Hogg, Meanwood, Leeds, had a large stand of bottled fruits, which secured a silver-gilt medal.

A silver medal was awarded to Messrs. Little and Ballantyne, Carlisle, for their interesting collection of fruit, such kinds as *Apples Peasgood's Nonsuch*, *Lord Derby*, *Maltster*, *Norfolk Beauty* and *Beauty of Stoke* being very good.

A vote of thanks was given to the Hunsingore and District Fruit-growers' Association for a collection of fruit.

For sixty varieties of *Potatoes*, Mr. William E. Sands, Hillsborough, Ireland, was awarded a large silver medal.

Mr. R. J. Foster, Stockell Park, Wetherby, Yorks (gardener, Mr. John Turton), had a small but well-grown collection of hardy fruits. *Pears Louis Bonne* of Jersey and *Durondeau*, and *Apples Rival*, *James Grieve* and *Charles Ross* were exceptionally fine. Good decoration in this exhibit showed off the produce to advantage.

Messrs. Webb, Wordsley, Stourbridge, were awarded a large silver medal for fifty varieties of *Onions*. We noticed that *Cranston's Excelsior*, *Webb's New Masterpiece*, *White Lisbon* and *Snowball* were well grown and solid.

Messrs. W. Seabrook and Sons, Chelmsford, were awarded a large silver-gilt medal for a stand of *Apples*, *Peasgood's Nonsuch*, *King of the Pippins*, *Bleuheim Orange* and *Allington Pippin* being outstanding varieties.

A second-class diploma was awarded to Mr. Yeld, York, for *Aster Celia*.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The monthly committee meeting of this society was held at the Royal Horticultural Society's Hall on Monday, October 14, Mr. Thomas Winter in the chair. One hundred and thirty-one new members were elected, being a record number. Gardeners have still an opportunity of making the United their approved society, and should fill up their forms at once. The sick-pay amounted to £38 13s. A grant from the Benevolent Fund to enable a distressed member to pay his contributions was made, also a grant to a member from the Convalescent Fund. One member was allowed to withdraw his interest. Business relating to National Health Insurance was also dealt with, and a sub-committee formed to advise upon any current business arising from the same.

EDITORIAL NOTICES.

Every description of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Winter and Summer.—In a Wiltshire garden, within a short distance of each other, the Winter and Summer Jasmynes are in full flower, and a Holly tree is glowing with scarlet berries.

A Dwarf-growing Loosestrife.—One hears from various quarters good accounts of Henry's Loosestrife, *Lysimachia Henryi*, which is a novelty now finding its way into a good number of gardens. It seems to be doing well, and is very pleasing with its procumbent stems and its terminal heads of orange yellow flowers. It bloomed for a considerable time this summer, and has been admired by many competent judges.

Record Price for Apples.—At the Kent Commercial Fruit Show held at Maidstone last week, and a review of which appears on page 568, six boxes of Bramley's Seedling Apples sold by auction realised £12. As each box held about three and a-half pecks, this is, of course, more than £2 per bushel. The fruits in question were packed and shown by Mr. G. E. Champion of Mereworth, Kent, and won the Coupe Challenge Cup offered for the best six boxes in the show. Every Apple was brilliantly coloured and perfect of its kind.

Fremont's Crane's-bill.—*Geranium Fremontii*, although not long introduced to gardens, has become a favourite with those who cultivate it. It is about a foot high, and has nice leaves and large purplish flowers of a light shade. This hardy *Geranium* flowers freely and for a long time in succession, and will thrive in any border of common soil. In the large rock garden it is also effective. Like most of the race, it blooms in summer. This Crane's-bill can be raised from seeds, and is also propagated by division of the roots in spring.

City of London Rose Society.—This new society was formed at a meeting held at the Cannon Street Hotel on Wednesday of last week, its objects being to encourage healthy competition among *bona-fide* City workers who are interested in Roses. Only those who actually work in the City of London itself, or who have offices situated therein, will be eligible for membership. The annual subscription will be 5s., and it is hoped that the Lord Mayor will kindly consent to act as president. The secretary is Mr. A. E. Protheroe, 67 and 68, Cheapside, E.C., and all applications for membership should be sent to him.

Verbascum Miss Willmott.—Miss Willmott's Mullein is a handsome garden plant, and the raisers are to be congratulated on having obtained permission to give it the name of a lady so devoted to gardening. It is not unworthy of the name, being one of the finest of all hardy summer-flowering perennials with white flowers. From its rosettes of big green leaves it sends up a towering spike

some five feet or six feet high, and produces in great numbers handsome white flowers some two and a-half inches across. It is truly a stately subject, and of grand effect in the border. Unlike many of our finest Mulleins, it is a perennial, and will remain in good health for a long time.

Late Roses.—On Sunday, the 3rd inst., we gathered in an Essex garden some excellent flowers of the following Roses: Richmond, Margaret, James Coey, Margaret Molyneux, Mrs. Alfred Tate, Gloire de Dijon and the Old Blush China or Monthly Rose. On the mornings of the 1st and 2nd inst. 7° and 9° of frost had been registered, but the Roses appeared none the worse.

A Fertile Form of Adiantum farleyense.—The magnificent stove Fern, *Adiantum farleyense*, must no longer be regarded as sterile, for its variety Gloire Van Moordrecht, introduced last year, has proved itself capable of producing fertile spores. Already the large Fern-growers of this country have succeeded in raising many thousands of young plants from spores. *A. farleyense* is a native of Barbados. It was introduced to this country in 1865, and has long been regarded as a barren form of *A. tenerum*.

Hornbeam Fruiting Well.—*Carpinus Betulus*, or the common Hornbeam, is a well-known deciduous tree, native of Britain. It forms a good hedge plant and withstands pruning well, while the leaves remain on after they are dead, thus affording good shelter. The dry fruits or seeds ripen at this season, and are now being well distributed by the wind. From almost every county come reports of the enormous quantity of seed produced this year. It is probably the greatest within human memory.

A Beautiful Birch.—In 1888 the late Mr. J. H. Veitch succeeded in introducing seeds of *Betula Maximowiczii*, a Japanese species, to England, and about five years later seeds or young plants were sent to Kew by Professor Sargent, Director of the Arnold Arboretum. It does not appear to have been introduced in quantity, however, judging from its rarity. In noticing it in the "Forest Flora of Japan," Professor Sargent refers to it as "certainly one of the most distinct and beautiful of all Birches, growing 80 feet to 90 feet high with a trunk 2 feet to 3 feet in diameter, with pale, smooth, orange-coloured bark." Its behaviour in this country up to the present indicates that the above remarks are applicable to it here, for its great vigour, handsome bark and large leaves make it the most conspicuous of the several species. The broadly-ovate leaves are 3 inches to 6 inches long, without reckoning the stalk, and are 2½ inches to 3½ inches wide. About May the male catkins, which are 3 inches to 4½ inches long, are showy, while in late summer the fruiting catkins, which are up to 4 inches long, are equally conspicuous.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Best Pears and Their Cultivation.—On pages 543-44 Mr. Bunyard has some valuable notes on Pears. I was most interested in his reference to varieties, and especially to Conference, Durondeau, Marie Louise, Emile d'Heyst and Doyenné du Comice. The last-named makes a grand wall specimen trained fan-shaped. Emile d'Heyst does well on a wall and also as a bush. It is not attractive in appearance like Durondeau, but its flavour is not surpassed by many other varieties, and amateurs with small gardens should be sure that it is added to their collection. Durondeau is a grand variety for growing as a cordon, and in this form produces some of the handsomest fruits among Pears. Marie Louise is generally grown on a warm wall, but it will succeed as a pyramid or bush.—B.

A Beautiful Autumn Border.—The illustration of the border of Michaelmas Daisies at Aldenham House, Elstree, which appeared on page 543 of the issue of October 26, is one of the best of these useful autumn-flowering plants I have ever seen. For many years past I have wondered why so many persons plant their Michaelmas Daisies in unattractive ways—isolated plants in odd corners, tied up like sheaves of corn. The plants shown in the illustration referred to look so charming that no doubt many readers will be induced to rearrange their plants and purchase more this autumn. The Michaelmas Daisy flowers at a season when outdoor blossoms are becoming scarce, and on this account alone it is well worth growing. Mr. Beckett, has, I believe, raised some very beautiful varieties.—AVON.

Polyantha Rose Ena Teschendorf.—Allusion is made to Jessie as a free-flowering form of Dwarf Polyantha on page 525, issue October 19, and although granting that Jessie is exceptionally free and desirable as a dwarf Rose, it is likely to be ousted from its popularity by Ena Teschendorf, a newer variety in the same section. The newcomer was sent out in 1911 by Teschendorf, and is a sport from Mme. N. Levavasseur. The flowers are a deep carmine red colour, quite like Grüss an Teplitz. It has the advantage of not losing its colour even in the hottest sun. In colour it is deep carmine red.—E. M. [We have not seen the variety Ena Teschendorf, but the great advantage of Jessie over others of its type is that its colour does not fade in brilliant sunshine.—Ed.]

Tobacco Plants and Earwigs.—In "Notes of the Week," issue October 26, a very interesting reference is made to amateurs and others refraining from growing Dahlias on account of trouble from earwigs. I have never heard that the Tobacco Plant will keep away these pests, but pennyroyal is supposed to drive them away from cupboards, rooms and greenhouses. I have tried this remedy—which is rather expensive—and found it efficacious. The liquid should be put on pieces of cotton-wool and laid near the things that are to be protected, though not on any foliage. Perhaps a few pieces of the wool saturated with the oil and placed near the stems of the Dahlias would keep the earwigs away.—G. G.

— I noticed in your issue for October 26, page 537, a suggestion that planting Tobacco Plants among Dahlias might keep off earwigs. As a matter of fact, I do not find that I am much troubled with earwigs among the Dahlias.

This year there has been quite a plague of earwigs, but I have found very few among the Dahlias. On the other hand, three plants of *Cobæa scandens* have been utterly ruined by them, the leaves and buds being absolutely destroyed, so that I have not had a single flower. In front of one of these *Cobæas*, in touch with it, are a number of Tobacco Plants (the ordinary flowering variety). This plant has suffered the worst of all, so the Tobacco Plants do not appear to be of any use in keeping off earwigs.—(Colonel) G. H. TILLARD.

The Deciduous Cypress Fruiting.—Although the Deciduous Cypress is a well-known tree in the British Isles, its cones are known to comparatively few, for it bears them shyly in this country. Even in the Duke of Northumberland's garden at Syon

A CONE-BEARING SHOOT OF THE DECIDUOUS CYPRESS. THIS TREE SELDOM FRUITS IN ENGLAND.

House, where so many fine and rare trees are to be found and the Deciduous Cypress is remarkably well developed and represented by many specimens, cones have not been noticed before the present year. Now an example, and curiously not one of the older trees, is bearing some hundreds of cones, while a few may be noted here and there about other trees. A few cones are also noticeable on the old trees at Whitton, while they have been reported from a few other localities. *Taxodium distichum*, the Deciduous Cypress, is a native of the Southern United States, where it grows over large expanses of swampy ground. It is peculiar by reason of the curious woody knees, which are produced from roots that are in the vicinity of water. These rise to a height of 2 feet or more, and are well developed about some of the Syon House trees. The tree is also able to live and grow, year in, year out, when the trunk is surrounded by water, a character not noticeable in many trees. In America the wood is in demand for many purposes, and is of great value for the manufacture of water tanks, on account of its great lasting qualities when wet. The tree is an ornamental one, its graceful foliage being a pleasing shade of pale green in spring and summer, and turning to deep crimson-brown in autumn. The illustration was prepared from a shoot collected at Syon House.—W. D.

Lilium Brownii.—The statement on page 553 that the varieties of *Lilium Brownii* are scarce in cultivation needs in one instance to be qualified, for Colchesteri is sent here from Japan in considerable numbers during the winter season; indeed, the *Brownii* of the Japanese is this particular variety. Taken altogether, *L. Brownii* is a most puzzling Lily, all that is known of its early history being that it was distributed by a nurseryman named Brown in the first half of the last century. Since then it has been cultivated by the Dutch, and, despite the assertion so often made that *L. Brownii* is a native of China, the fact remains that the form long grown in Europe is quite distinct from any that we have had sent from China within recent years. Whether the change has resulted from an extensive period of cultivation I cannot say, for I have known the Dutch *L. Brownii* for the last forty years, and it has not varied one whit in that time. There is no doubt that the European and Chinese kinds are but forms of one Lily, but on the score of priority the specific name of *Brownii* must belong to that grown by the Dutch. A perusal of the "Kew Hand List" tends to confuse rather than elucidate the situation, as there *Colchesteri* is separated from the other forms of *L. Brownii* and is regarded as a variety of *L. japonicum*.—H. P.

Iris Snow Queen.—It would be interesting to know whether the writer of the note on *Iris Snow Queen* on the first page of the issue of THE GARDEN for November 2 has any evidence for his belief that the plant is a hybrid. I should like to put forward the view that this fine *Iris* is merely the albino form of the *Iris orientalis* of Thunberg, which is probably a good species and entirely distinct from *I. sibirica*. It is possible that the two plants merely represent different combinations of pairs of Mendelian characters, but this possibility has still to be proved. All that appears to be proved at present is that *I. sibirica* has tall stems, raising the flowers well above the foliage, and produces heads containing three, four or five flowers on pedicels of increasing length. The capsules are short, broad and bulging, and contain large, flat seeds. *I. orientalis*, on the other hand, has leaves which, if held erect, are as long as, if not longer than, the stems, of which the terminal head rarely contains more than two flowers on comparatively short pedicels. The capsules are long and narrow, triangular in section, and contain small, thick, almost cubical seeds. As regards the actual flowers, those of *I. sibirica* are distinctly smaller than those of *I. orientalis*, and, moreover, the almost orbicular fall-blades of the latter are extended nearly horizontally, while those of *I. sibirica* hang perpendicularly. Of both these *Irises* albino forms occur, among which there are individual differences both in vigour and in floriferousness. *Snow Queen*, the albino form of *I. orientalis*, breeds true to the white colour, and is a recessive for the colour factor. If the type and the albino form be cross-fertilised, some very beautiful forms of a bright sky-blue colour can be obtained, of a shade that I have not seen elsewhere among *Irises*. It is not quite certain how the name of *I. sibirica* came to be applied to a plant which seems to be confined to Central Europe and Russia west of the Urals, but the evidence of herbarium specimens seems to prove that *I. sibirica* does not extend east of this line, and that *I. orientalis* is not found west of the neighbourhood of Nertsinsk in Manchuria, whence it extends through Korea into Japan.—W. R. DYKES, *Charterhouse, Godalming.*

Cattleya Maggie Raphael.—As a winter-flowering *Cattleya* this is a great acquisition, being obtained from *C. aurea* and *C. Trianae*. It combines the good qualities of both these fine species, and in instances where *C. Trianae alba* has been employed as a parent the result is even more pleasing. In this case the sepals and petals are white, while the lip is purplish, with distinct golden yellow markings in the throat, which are inherited from *C. aurea*. Wherever *Cattleya* flowers are required, this hybrid should certainly be added to the collection.—S.

Narcissus minimus for the Rock Garden.—Judging from the exclamations of delight with which my friends greet this little Daffodil when they visit my garden, it is to a very large number of gardens not so much known as its dainty minuteness deserves. While it is common knowledge that there is a class of dwarf *Narcissus* suitable for rock gardens, few who have not actually seen it realise how dwarf this species really is. Thinking to bring this home to my friends who are not able to see the little flowers themselves, I took the accompanying photograph. Everyone knows the large yellow trumpet Daffodil Emperor; by cutting a flower of this and inserting it near a colony of the wee *Narcissus minimus*, a comparison of their real size is disclosed, which is much more telling than a long wordy account of them. Not only is *N. minimus* small, but it is perfect in every detail, closely resembling Emperor in form. No rock gardener who does not already possess them should miss the opportunity of obtaining and planting now one or two groups of these sweet little flowers, selecting any spot in the rock garden open to the sunlight for them. No special treatment appears necessary beyond working in some leaf-soil and sand about the spot they are to occupy in the already well-grained rockery.—REGINALD A. MALBY.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Continued from page 556.)

Rocks, Natural and Artificial.—The question of suitable and unsuitable rocks in the making of a rock garden is, naturally, of some importance, and much depends on a good, or, shall I say, a right selection. For present purposes, however, those named above, the "natural and artificial," merit careful attention. For the moment, too, one might dismiss the latter and concentrate attention upon the former. Natural rocks, it should be stated at the outset, are of two kinds, the suitable

The Great Oolite from the same range of hills is, on the other hand, good in colour, in the size and variability of the available blocks, in its stratified character, and sympathetic and nourishing withal. Naturally, limestones are exceedingly variable, and those of Derbyshire and Yorkshire not only differ from each other, but materially so from those of other localities. In the main, however, limestones may be cited as the most serviceable and important of all stratified natural rocks, and because of their boldness or picturesqueness are pleasing to the eye and do not, for any lengthened period at least, detract from the plants themselves; that is to say, they are quickly brought into submission, and, weathering down by exposure and climatic influences, soon lose their one defect of quarried newness, should this exist. That it may not exist is proved by the frequent presence of "weathered limestone," which, assuming a dull grey tone, is a charm indeed.

Another type of limestone is the Purbeck, found in the neighbourhood of Swanage. In its selected form it is ideally beautiful and picturesque, admirably suited to vegetable-life, available in large or small blocks, and, presently toning to a marl brown, is difficult to surpass. In point of colour—and colour is not to be ignored—this and the great oolite of the Cotswolds appeal to me before all the other limestones. Both, too, are of the greatest value when used in conjunction with water in the rock garden. Thus it will be seen that this most important of rocks is available North and South, and in many other directions also; hence rock garden builders should take note.

Sandstones.—These come next in importance to the limestones, and, like them, are of a greatly varied class—good, bad and indifferent. In Surrey and Kent, Worcester and Cheshire, Warwick and Sussex and other parts, examples of this rock occur, now of wall-like massiveness, or, anon, shaly and thin and of no value to the rock garden builder. Occasionally, however, these thin slabs of rock—probably for the sake of cheapness alone—are employed, and, upended as they most usually are, constitute a good object-lesson of what not to do in rock garden building. Slabs of this rock 3 feet

NARCISSUS MINIMUS, WITH A FLOWER OF EMPEROR FOR COMPARISON OF SIZE.

FORTHCOMING EVENTS.

November 11.—National Chrysanthemum Society's Floral Committee Meeting.

November 12.—Chrysanthemum Shows at Belfast (two days) and Plymouth (two days).

November 13.—East Anglian Horticultural Club's Meeting.

Chrysanthemum Shows at Brixton, Colchester, Lancaster, King's Lynn (two days), Buxton, Bristol (two days), Barry (two days); and of the Liverpool Horticultural Association (two days).

November 14.—Chrysanthemum Shows at Romford, Hitchin, Barnsley (two days), Sheffield (three days), Edinburgh (three days), Newport (Mon.), Bridgwater, Aberdeen, Cardiff; and of the Scottish Horticultural Association (three days).

November 15.—Chrysanthemum Shows at Macclesfield (two days), Blackburn (two days), Huddersfield (two days), Bolton (two days), Bradford (two days), Kilmarnock, Stockport (two days); and of the Leeds Paxton Society (two days).

and unsuitable, *i.e.*, the sympathetic and nourishing, or the reverse. Quite naturally, too, it is the sympathetic and nourishing which we require, and into this category fall the majority of limestones and sandstones. One uses the word "majority" studiously, inasmuch as certain classes of rock—the inferior oolite of the Cotswolds, for example—crumble quickly under the influence of frost and exposure; hence a rock garden of such material would soon be crumbling to decay, with, possibly, serious results. The magnesian limestone of the same district is also unsuitable, its glaring whiteness—approximately that of chalk—being much against its use.

or 4 feet across are sometimes seen; but, save as stepping-stones in the water garden or as pathways in the rock garden itself, there is little use for them. Most usually—almost invariably—sandstone may be regarded as of a sympathetic nature to vegetable-life, to which the built sandstone walls of Cheshire and the unquarried rocks of many parts bear ample testimony. Ferns, Mosses and other plants appear to take most kindly to it, and the fact is of untold value to the gardener. Rugged, too, or picturesque in some instances, and porous and moisture-absorbing to a degree, it is greatly to be desired for the purpose one has in mind.

For rock building, however, I should place the red sandstone first, that of the old red sandstone formation more particularly, by reason of its rich warm colour, which contrasts so effectively with plant-life. Its porosity and coolness are of value, and its more exposed parts are soon moulded by wind and storm. Some of the Sussex sandstones are good and effective, others are perhaps a little formal, and, unless intelligently handled, present that appearance in the garden. Some types of sandstone, like those of the other great formation first referred to, are quickly rent by frost; hence care is necessary in the selection of them, if not even some sort of guarantee of their durability in this respect. Apart from the rocks already mentioned as suitable, there are others known as tufa and millstone grit. Both are excellent for plant growth, and in good hands are capable of affording effective results. On the question of expense, the first-named for outdoor work may at once be dismissed. It is perhaps less good and less nourishing than some of the limestones, though of a highly decorative class.

Highly-fossilised rocks, such as those of the gryphaea and ostrea, of the oolite marl of the Cotswolds, and others which in Nature have become crystallised by contact with igneous rocks in the molten state, I regard as unsuitable for rock gardening in general.

Perhaps the least suitable of all natural rocks for the purpose in view is granite, primarily because of its impervious and unsympathetic nature.

E. H. JENKINS.

(To be continued.)

TREES & SHRUBS.

EVERGREEN RHODODENDRONS.

IN gardens large and small, where the soil is deficient in lime, Rhododendrons are the best flowering evergreens to plant. The transplanting may take place at almost any season, although autumn and spring are unquestionably the best times.

A small collection of Rhododendrons might include the following named sorts: Pink Pearl, Gomer Waterer, Mrs. E. C. Stirling, Mrs. Tom Agnew, Lady Grey Egerton, Alice, Lord Palmerston (Cynthia), Doncaster, Lady Clementina Mitford, Mrs. Holford, Snowflake and John Waterer. The named varieties are so numerous, however, at the present day that, were a request sent to ten of the leading Rhododendron-growers for a list of the twelve best sorts, fifty names at least would probably be given. In addition also to named sorts, raisers of seedling Rhododendrons in quantity have usually a stock of plants for disposal which, though not quite up to the standard to introduce as new named varieties, are too good to destroy

SHRUBS FOR TERRACES.

The practice obtains in some gardens of cultivating plants of various descriptions in tubs for use on terraces during the summer and autumn months, and as a number of enquiries have been made of late respecting plants which are suitable for the purpose, some suggestions are appended as a guide for those who wish to take up this method of plant culture.

It is, as a rule, necessary that some fairly light structure should be available for the winter storage of the plants. This was met in the time of our forefathers by a building called an orangery. It was a rather heavily-built structure, with a slate roof, a blank wall at the back and front, and sides

go for several months without water. When water is given, however, it must be in sufficiently large volume to thoroughly soak the ball of soil and roots.

The common Bay, *Laurus nobilis*, is popular for terraces, grown either as a pyramid or a standard, but it is overdone, and there are other plants which might very well be substituted for it. A return to the old habit of growing standard Oranges for the purpose is to be commended, for when plants such as those at Mount Edgumbe and Margam are seen they command great respect. Unfortunately, the more easily-grown Bay has to a great extent supplanted the Orange. The common Myrtle, *Myrtus communis*, is another shrub which might be widely grown, for its fragrant

leaves make it popular, while its white blossoms and black or deep purple fruits are very showy. The small-leaved variety, *terentina*, is also an acquisition. Care must be taken to let the Myrtles develop freely, for they are not nearly so attractive when clipped hard, as is often done with the Bay. *M. Ugni* is another showy kind. *Clethra arborea*, the Lily of the Valley Tree of Madeira, is another excellent plant. It will grow quite 15 feet high, and is showy alike by reason of its dark green leaves and white flowers. Several well-grown and well-flowered plants were seen growing in tubs at Hampton Court a short time ago. *Acacia armata*, although usually considered purely as a greenhouse plant, may be used quite well as a terrace plant during summer, for it may be grown into a handsome specimen at least 10 feet high. The Pomegranates, *Punica granatum* and its variety *nana*, are well grown in some gardens, and when covered with scarlet flowers they are very handsome. Although more often included as a border plant, *Choisya ternata* is quite a good shrub for tub culture, its foliage and flowers alike being ornamental. Fuchsias may be used with effect, as also may large plants of *Hydrangea hortensis*.

Agaves are familiar objects in many gardens, although they must be used with caution in places where children are in the habit of running about, for the ferocious

A SEEDLING RHODODENDRON AT ITS BEST.

fitted with large windows, which reached from the top of the building to the floor. Between the windows rather wide stone or brick pillars were arranged. The building was unheated, save sometimes by a fireplace. As modern requirements go, such a structure would not be considered an ideal one for plants, but it served its purpose well, and there are gardens in the country where such an orangery is still put to its original use.

The essential points to observe throughout winter are that the plants must be very carefully watered and that fresh air must be admitted at all times. In the event of the soil being fairly moist when the plants are housed, they will usually

spines which arm the leaves are a source of danger. In sunny gardens the Oleander, *Nerium Oleander*, may be used with effect, although it rarely gives such good results in this country as are usual in Southern Europe. Conifers, as a rule, are not to be recommended for this class of work, but a great deal may be done with Camellias. When small plants are required, the Tree Ivies come in excellently, while some people form screens of trailing kinds to block out undesirable objects. Many other plants, such as *Escallonia macrantha*, *Elaeagnus* species, *Umbellularia californica*, &c., will suggest themselves, but enough has been written to direct attention to some of the best.

THE FLOWER GARDEN.

SWEET PEA NOTES.

A Histon List.—Histon in Cambridgeshire has long been celebrated for the splendid crops of various kinds which excellent culture on good land has produced; but it has come into immensely greater prominence in recent years because it is the home and headquarters of Mr. W. J. Unwin, one of the cleverest of modern Sweet Pea specialists. He made his name with Gladys Unwin, which quickly became the most popular of all Sweet Peas for market culture, and in the seasons which have intervened since its introduction Mr. Unwin has not failed to give us novelties, and almost invariably they have been conspicuous for many good points and the fact that the proportion of trueness was always exceptionally high, this latter fact being attributable to the extreme care that is exercised with the Histon stocks.

In this present season Mr. Unwin is offering four novelties of his own raising. Mrs. D. Denholm Fraser may be most accurately described as an Earl Spencer Mrs. W. J. Unwin, which will suffice to mark it as a variety that must be grown by those who are partial to the refined flakes of these days. Muriel Quick has a white ground with light blue veins; the size and form are alike excellent. Victor Unwin is a deep chocolate that seems to be quite distinct from any other variety of the Spencer group. The Abbott was not raised by Mr. Unwin, but by Mr. W. Lumley, of Constance Oliver fame. It is peculiar in colour, though all of us would not regard it as strikingly attractive. The ground is very light grey, with suffusions and venations of grey-brown or brown. It would certainly be distinct in a stand of exhibition flowers, for which it possesses the necessary size and form. Dora Hopley is identical in colour with Mrs. D. Denholm Fraser, but it belongs to the smooth or grandiflora group. Mr. Unwin also offers several novelties of other firms' raising, as well as all the leading standard varieties. I must put in a brief word for Eric Harvey. It has not attained to the popularity to which its conspicuous beauty indisputably entitles it, and this is, perhaps, due to the fact that it thrives magnificently in some soils and districts, but fails to do itself anything approaching to justice in other places. It ought to be tried, and, if it fails, then it must go; if it succeeds, the grower will not require any inducement or persuasion to grow it again. At one of the August shows of the Royal Horticultural Society, Messrs. Bide and Son staged a vase of flowers of it that were superb in colour, size and form.

A Winchester List.—Those of us who have never wavered in our allegiance to the National Sweet Pea Society will remember the time when Mr. C. W. Breadmore came from Winchester and swept the boards in all the competitive classes in which he was entitled to exhibit, and thence onwards he has been prominent in the cult. From the early days he gave us novelties of outstanding excellence; but, unfortunately, they did not invariably come true to name. However, the merits

were unquestionable, and the varieties have lived where others of inferior quality have been long ago forgotten.

This season there will come from Winchester Aggie Elder, which is a real beauty in colour and form, but is near to two or three which are blessed with different names; the shade is glowing cerise. Princess Mary is blue, deeper in the wings than the standard, and the size and shape leave nothing to be desired in an exhibition Sweet Pea, while for the colour alone it ought to be grown for decoration. May Henderson is a pure deep violet of Spencer form, for which a place will have to be found. The additions to the cream pinks are bewilderingly numerous, and it is not always easy for the tyro to see striking differences. Mr. Breadmore's variety in this group is Mrs. Fred Arey. Iris, salmon, is too well known and admired to need special commendation here. Others which are offered in the same list are Frilled Cream; Lord Curzon, magenta; King Alired, orange pink; Jack Tar, blue; Mrs. Holroyd, maroon; Annis Gibson, purplish mauve; and Flossie Jeffery, a soft shade of Iris. There are, of course, the

A FINE BORDER OF MICHAELMAS DAISIES WITH EVERGREEN SHRUBS AS A BACKGROUND.

many standard varieties in addition to those named.
HORACE J. WRIGHT.

A BORDER OF MICHAELMAS DAISIES.

A BORDER of Michaelmas Daisies makes one of the brightest features of an autumn garden. When planted in a well-chosen site, for preference against a dark background of evergreen shrubs, a most cheerful effect is produced. A particularly well-planted border at Kew is seen in the accompanying illustration, in which the tallest-growing plants are kept in the background. The tall variety here depicted is Finchley White, while Feltham Blue and Robert Parker occupy the foreground.

There is no lack of varieties, and, in addition to those mentioned, a good selection would include Climax, clear light blue with flowers 2 inches across; St. Egwin, soft pink, 18 inches; Star Shower, creamy white flowers borne in profusion, 3½ feet; and Ericoides, with Heath-like foliage and small white flowers, 3 feet,

COLOURED PLATE.

PLATE 1458.

TWO GOOD COTTAGE TULIPS.

WHEN I wrote my notes on Tulips for last week's issue, I had no idea that such a plate as this was about to appear. If readers will refer to what I said there about Moonlight, they will see that my opinion of it is a very high one indeed. Its earliness and its beautiful pale primrose colour commend themselves to me. It is also a wonderful laster; otherwise it would not have been possible to paint these two varieties together. For as Moonlight is one of the earliest of the Cottage section, so Mrs. Kerrell is one of the later ones. Neither of them is a tall grower, and of the two the last-named is the shorter. As may be seen from the plate, it has a bloom of quite a different type to the exceptionally long flower of Moonlight, inasmuch as its petals reflex,

and in its young state (the top flower on the plate) it is vase-shaped or, as I have got into the way of describing such forms, "waisted." Unfortunately, the colouring of the plate gives one the idea that it had been to the rouge-pot before sitting for its picture. I have grown it for a long time, but I have not seen it so rosy. There is a good deal of amber or buff associated with the pale warm pink, and the whole is not without a suspicion of lavender. It is a very lovely flower, but a most difficult one to describe. I may mention that both varieties are very popular among the visitors to my garden. In common with all other kinds of Tulips, these may be successfully planted during the next week or two, or even well into December, though very late planting usually results in rather short stems. This, however, is not a very serious drawback, especially where garden decoration is the main object. The flowers from which the coloured plate was prepared were provided by Messrs. Barr and Sons,

JOSEPH JACOB.

A BOLD FLAGSTONE PATHWAY IN THE SUNK GARDEN BORDERING THE KITCHEN GARDEN AT CARROW ABBEY.

erect, and good habit of growth. It is also fragrant, a Continental Rose of merit, and distinctly above the average. It was one of a list of twenty new Roses that Mr. Mawley annually asks the opinion of the leading nurserymen and amateurs to place in order of merit, and I shall be much surprised if it is not found in the top half of the table. It has been well and frequently shown this season, and bears x x x in my own list as growing here, so those who have not grown it may, I think, add it to their list to get. It is one of the bicolors, two shades of carmine and pink.

Juliet (William Paul, 1910).—I do not grow this Rose, but I should not like my personal prejudice to prevent others from so doing. It has frequently been exhibited, and those who like its colour should not fail to try it. It is a very strong grower, but, producing its flowers at the end of each growth only, it cannot be called free-flowering. To my way of thinking its chief point of merit is its fragrance, which is very marked. I have heard it described by a lady as "the most beautiful" of all Roses!

Lady Alice Stanley (S. McGredy and Son, 1909).—Another bicolor, and possibly one of the best, as its flowers are held erect on good sturdy growths; colour, pale flesh pink, with the outside of the petal (which one must remember in a show flower is the side that shows the most) deep coral rose, a combination of colouring that is both pleasing and distinct. The flowers come of good shape, and I wonder more is not seen of it on the exhibition bench. It must be cut young, and resents

death. It is quite simple to grow them in an ordinary unheated greenhouse, but during the very severe weather in midwinter no flowers will be produced. During the autumn, spring and summer, however, excellent results should be obtained.

As plants to grow out in the garden there is little fear of frost killing them. Their greatest danger is excessive moisture at the root; therefore an open, well-drained situation is desirable. The plants will then flourish from June until the first severe frost of winter. There is no doubt as to their superiority over the ordinary border Carnation now that their hardiness has been proved.

In the matter of propagation, the common practice is to root cuttings from plants grown under glass during the winter and early spring, while layering is usual with plants grown in the border. MONTAGU C. ALLWOOD
Hayward's Heath.

it this autumn, so I must preach what I practise and say, "Not recommended."

Jacques Vincent (Soupert et Notting, 1909).—Beautiful, but not big enough for present-day standards. Not recommended.

Jonkheer J. L. Mock (Leenders, 1909).—This is a fine Rose, coming of good size, flowers carried

AN AUTUMN BORDER IN THE SUNK GARDEN IN THE GROUNDS AT CARROW ABBEY, NORWICH.

THE ROSE GARDEN.

NOTES ON NEWER ROSES. HYBRID TEAS.

(Continued from page 555.)

His Majesty (S. McGredy and Sons, 1909).—If one could only keep the mildew away, this variety would be worth growing; but it is almost as great a sinner in this respect as Her Majesty, and they would make an excellent pair for any mildew preventive producer to try his specific on before introducing it to the British public. For this reason it has been a disappointing Rose with me, and I have (reluctantly, I admit) discarded

tying. Habit of growth excellent, not particularly tree-flowering, but it is very fragrant. It was awarded the gold medal of the National Rose Society, and, I think, deserved it.

Lady Barham (Alex. Dickson and Sons, 1911).—This is a fine exhibition Rose of very large size; colour not unlike Maman Cochet, deep flesh pink; but it requires a warm sun to open its numerous petals. The growth is strong but robust, certainly not vigorous, and the flowers are, consequently, held erect. A dependable flower, guaranteed not to flag in the exhibition tent.

Lady Greenall (Alex. Dickson and Sons, 1911).—I am not sure that this Rose should not more fittingly be noticed under garden or decorative Roses; but I have had one or two such fine flowers that I am going to include it here, though it is undoubtedly a garden Rose first and all the time, and an exhibition Rose only occasionally. This is one of the aristocrats among Roses, not a great number of petals, but sufficient; a good grower, fine foliage, erect, fragrant, beautiful in shape and colour. The latter varies, but a deep creamy white outside petal, deepening to intense golden orange in the centre, very inadequately describes it.

Southampton. HERBERT E. MOLYNEUX.

(To be continued.)

THE KENT COMMERCIAL FRUIT SHOW.

ON more than one occasion we have referred to the slipshod methods of grading and packing Apples and Pears for market by growers in this country, and in our issue for August 31 we published an illustrated article by Mr. E. A. Bunyard on packing as adopted in Canada and other of our Colonies in the hope that it would be of assistance to growers in this country. That this system of grading and packing in boxes must be adopted if our home growers are to compete with the Colonial fruit that now holds the market, everyone in a position to express an opinion is agreed; hence the efforts of the Kent Fruit Growers' Association and the Wye Agricultural College in this direction are worthy of the highest praise.

The exhibition held in the Corn Exchange, Maidstone, on Tuesday and Wednesday of last week was, to put it in the words of a large Covent Garden salesman, worth pounds as an object-lesson to fruit-growers in this country. All the classes were for commercial fruits, *i.e.*, Apples and Pears,

as they would under proper, up-to-date methods be sent to market, and all had to be graded and packed in Federation boxes or half-boxes, these being the same size as those used in the Colonies. That the exhibition was regarded as of the utmost

A BOX OF PEARS PACKED AND SHOWN BY MESSRS. GASKAIN AND WHITING AT THE KENT FRUIT SHOW.

importance was demonstrated by the number of salesmen and commission agents from Covent Garden who attended on the first day, and who were eager to buy, at high prices, the best graded and packed Apples that were shown.

Undoubtedly the English grower at present is somewhat handicapped when competing with Colonial growers. Many good Apples that are grown in this country are unsuitable for box-packing, owing to their soft flesh, which is easily bruised, Warner's King and Peasgood's Nonsuch being cases in point. Then, again, home growers

of the box. In either case bad bruising would result. That this bad packing was, in a large measure, due to improper or insufficient grading was very evident. It is impossible to pack Apples firmly and securely in boxes unless the fruits are all of one size, and home growers will need to pay close attention to this point in future.

Two grading-machines were at work in the exhibition, one being suitable for small growers, and the other, an automatic machine that will grade over a ton of fruit per hour, being recommended for those who grow and market large quantities of fruit.

Although in many instances the grading and packing of the exhibits left much to be desired, there were a number of boxes shown that were superior in quality and packing to any Colonial samples that we have seen. The six boxes of Bramley's Seedling shown by Mr. G. E. Champion of Mereworth, and which won the Coupe Challenge Cup for the best six boxes in the show, were perfect, and the leading Covent Garden salesmen present were unanimous in the opinion that nothing approaching them had ever been sent to this country from abroad. This proves that the home grower, providing he will see about setting his house in order and introduce up-to-date methods on intelligent lines, can compete with Colonial growers, in spite of the natural advantages that the latter enjoy, and regain at least a good portion of the custom that has been captured by the more up-to-date growers abroad. The cultivation of suitable firm-fleshed varieties, such as Bramley's Seedling, Ribston Pippin, Blenheim Orange and, for earlier use, Worcester Pearmain, is a point that will have to be very seriously considered; but the exhibition and demonstration at Maidstone last week proved beyond a doubt that it is by no means impossible for English growers to compete with those in the Colonies.

We were pleased to see Lord Lucas of the Board of Agriculture present, because there are many directions in which the Board could, if it would bestir itself, assist growers of fruit in this country.

At present very little of a really practical nature is being done; but, judging by the statements made by Lord Lucas at the luncheon, more will be done in future. The stamping out of diseases, or at least greatly lessening them, by legislation, and the appointment of inspectors to see that it is done, has already been attempted, to some extent successfully, and it was pleasing to learn that investigations and experiments of various kinds among fruit are to be conducted, under the aegis of the new Horticultural Board, at the Bristol University, the John Innes Institute and Wye College. But,

GENERAL VIEW OF THE APPLES SHOWN AT THE KENT COMMERCIAL FRUIT SHOW.

have yet much to learn in the way of grading and packing. A careful survey of the exhibits staged at the show revealed the fact that a great many boxes were either packed too loosely or the fruits were bulging out too much above the surface

after all, growers must very largely work out their own salvation. As Mr. Dunstan, the Principal of Wye College, remarked at the luncheon, English growers have been too long content to hide their light under a bushel—the old bushel sieve, we presume.

GARDENING FOR BEGINNERS.

A LIVE GARDEN SHELTER.

WHERE there is space available in the garden or on a lawn, a structure such as that depicted in the illustration makes a novel and beautiful little summer-house. It is composed of withes—the young lithe growths of the Willow used by basket-makers. These should be procured at any time between November and February, and each be 9 feet to 10 feet in length.

When about to construct such a summer-house, a decision must be made as to the desired circumference, but this should, preferably, be not more than 12 feet. The plan should then be staked out and a trench 18 inches deep dug out round the stakes save for a narrow space where it is intended the opening shall be. It is well to arrange that the opening faces the morning sun; this will ensure that the interior is warmed up occasionally, and that the later, hotter rays of the sun are excluded when the shelter is likely to be occupied.

Having dug the trench, the withes are planted at intervals of 2 inches and rammed down very firmly. When all are planted, the tops are bent inwards—interlaced where possible—and secured together by string, thus forming the roof. Then, beginning near the ground, lengths of the withes are interwoven, basket fashion, among the uprights all around, and the process is repeated right to the top, with intervals of about one foot between them. Here and there, but not too frequently, these horizontal binders should be secured with strong bast to a stout upright, thus ensuring greater rigidity. Slips from the common Willow strike so easily that by the beginning of May the withy wigwam will have taken root and the young growth be showing at every eye throughout the structure; and with the advance of summer the whole will be a cool, shady nook and a decidedly picturesque addition to the garden.

W. JAMES ROBERTS.

HINTS ON PURCHASING ARTIFICIAL MANURES.

THE valuation of manures quoted in an invoice, so as to get at their cost per unit, is a simple matter, and it affords a rough-and-ready indication as to value received. It is a little more complicated where a compound manure is under consideration, but it is in all cases a necessary process, as one manure can be readily compared with another in value by no other rapid and reliable method.

The Fertilizers and Feeding Stuffs Act is precise and simple in defining what is required, as this is confined to a statement of the percentage

contained of nitrogen, soluble and insoluble phosphates, and potash. If these terms are adhered to in the invoice, the price per unit is easily ascertained, and they should be insisted on. If subterfuges in the form of analogous or misleading terms are quoted, instead of these, the buyer is not so sure of his ground, because the chemical composition can be altered to match them in a variety of ways. For example, if the potash is quoted as "potash salts," the percentage may represent only about

most likely to overlook the discrepancies of description. These may be put down as "total phosphates," *i.e.*, both soluble and insoluble together, a very misleading way of stating the percentage, because the insoluble may or may not be of value, according to the kind of manure.

Another stumbling-block is the expression "bone compound," at any rate where only dissolved bones are required, because it may contain phosphates from various sources as well as bones, a good deal cheaper and perhaps more insoluble. For it is especially to be noted that the Act does not stipulate for a statement of the source whence any manure-making material is obtained, only *how much* of the ingredients mentioned it contains. It is for this reason that, in compound nitrogenous manures especially, it is impossible to get at the correct value from the figures, because the sources of nitrogen are so varied; and in the organic form, which is largely used in compound manures, the value differs a good deal, though all appears as "nitrogen." This is unavoidable, and, if the purchaser is not satisfied, it is best to buy a manure of known origin, such as fish, blood, or meat, of which the prices can be readily compared together on their known merits.

It is well to bear in mind that, under the Act of 1906, purchasers are further safeguarded. One rather important clause provides that the actual percentages must be stated, and not merely the minimum, in the case of manures artificially made, for it is in them that most of the variation occurs.

GERVAISE TURNBULL, F.L.S.

A LIVE GARDEN SHELTER MADE WITH OSIER WANDS.

half the equivalent of pure potash—the amount found in sulphate or muriate of potash—or very much less. These two are far more concentrated, for example, than kainit, which only contains about twelve per cent. of pure potash, and it is for this reason that kainit is best applied a little ahead of crop requirements, so that the accompanying impurities may be washed out.

Another point that puzzles some people is "nitrogen equal to ammonia," whereby the latter appears greater than the former in amount by the proportion of 17 to 14, because ammonia contains three parts of useless hydrogen. It is an old custom without much, if any, meaning, and the buyer should see that he does not confound the two. It is, perhaps, with phosphates that the buyer is

are over. The first, *Aconitum Wilsonii* (one of Wilson's introductions from China), is a tall, bold-growing plant that will reach a height of 5 feet to 6 feet. The flowers, borne in an erect, terminal spike, are of a pleasing shade of violet blue, with the hood-like portion of the flower much developed. In this species, when the blossoms on the terminal spike are past, secondary ones develop rapidly and continue the display for some time. The other species, *A. Fischeri*, has in some unaccountable way been confounded with the preceding, but it is quite distinct therefrom. This only reaches a height of 18 inches to 2 feet or thereabouts, has pretty glossy leafage, and the flowers, which are of a lighter blue, are borne in shorter and denser spikes.—H. P.

TWO LATE - FLOWERING MONK'S-HOODS.

Two Monk's-hoods well represented in the long herbaceous border at Hampton Court, are not only valuable for their highly-ornamental qualities, but also for the fact that they bloom in the autumn, when nearly all their relatives

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Hyacinthus candicans.—This stately bulbous flowering plant is of easy culture, and will thrive equally well in the herbaceous borders or in a piece of ground that has been well worked in the shrubberies, and, being perfectly hardy, may be planted now.

Herbaceous Borders.—Undoubtedly, if it can be arranged, the present is as good a time as any for replanting or carrying out any alterations in connection with these, as by so doing the plants get settled before really hard weather sets in.

Spring Bedding.—Complete any planting that may be in arrears, both of plants and bulbs, as speedily as possible, always reserving a few plants of each subject for making good any gaps in the spring. Last year especially Wallflowers and *Myosotis* fared very badly. Continue to plant bulbs for naturalising, and the surroundings under a tree that has a clear stem in the smallest garden can be made a beautiful sight by planting indiscriminately the various coloured Crocuses. Erythroniums, Muscari, Scillas, Aconites and Snowdrops may all be planted in various open positions with the same hope of success, and the sooner it is accomplished the better.

The Rock Garden.

Tellima grandiflora.—This plant is now with us one of the most beautiful sights in the garden, and deserves planting entirely on its merits for autumn colouring, continuing good for a lengthy period. Such a plant as this, when placed near to some of our silvery-foliaged plants, is seen to the best advantage, and all should bear it in mind and include as many plants as possible, which are a source of attraction when the bulk are past.

Viola pedata bicolor.—This has been in flower now for some time, and the beautifully-coloured flowers on long, stout stems cannot fail to be noticed. This is a plant that one can thoroughly recommend.

Plants Under Glass.

Roses.—Where very early blooms are in request and the means permit of obtaining them, a few plants should be introduced at once. The pots should be well washed, the drainage made clear, and a little top-dressing afforded the plants after the necessary pruning has been done. Any Roses now in the stove may be potted with advantage, as they will be found to root well when placed back and plunged in leaves or ashes. Avoid over-potting, use just sufficient but perfect drainage, and cover the crocks with some turfy loam. The compost will consist principally of loam, to which should be added some lime rubble, wood-ash and a little soot, and, according to the nature of the loam, so vary the proportion of leaf-mould or spent Mushroom-bed manure.

The Hardy Fruit Garden.

Root-pruning.—Hardly a season passes but what one finds some tree or another which would not benefit by this operation, and it is also one of the most interesting to observe. Young trees, especially until they become established and fruitful, often require the main roots curtailed each year, especially when planted near to a border of particularly good soil, as is often the case. Commence by taking out a trench round the tree, starting from a radius of 2 feet to 3 feet, according to the size, but preferably the latter distance. Then with a fork gradually work away the soil from the ball into the trench, combing for the roots, and cut back any gross growers devoid of the fibrous roots so essential to a good fruiting tree. Any damaged roots should also be cut away with a sharp knife, and always from the under side in a short slant towards the operator. Gradually put back the soil, place any roots in position, and for stone fruits add some lime rubble to the soil and make quite firm by treading.

Fruits Under Glass.

Figs.—For very early supplies of Figs under glass, the trees, whether in borders or accommodated in pots, should be got in readiness and everything prepared for the time to close the house. Figs are frequently dirty subjects, very liable to

infection with mealy bug, and while the trees are dormant every effort should be made to rid them of this pest. Undoubtedly the best method is to cyanide the house, and when properly carried out by a capable person there is little danger. Successional washes with paraffin emulsions and thorough cleansing of the house and woodwork will do much to combat the trouble. As soon as the plants are subjected to a little heat, and before growth gets too far advanced, on a bright day many insects may be killed by touching them with a little methylated spirit.

The Shrubberies.

Planting.—This may be carried out at any time when the weather and state of the ground permit. On heavy lands, if possible, avoid doing so when the ground is too wet. The variety of material is very wide, and subjects suitable for all positions may be found. For general effect in the shrubberies aim at a suitable intermingling of evergreen and deciduous subjects, so that too much bareness does not exist at this season, and plant so that the season of flowering is prolonged. Evergreens make a fine setting for the flowering shrubs, and if the commoner ones are utilised in the background, they make excellent shelter for more tender shrubs.

The Kitchen Garden.

Jerusalem Artichokes.—As soon as convenient now, cut down the stems of these plants and burn them with other refuse on the smother fire. Lift a few of the tubers if wanted for immediate consumption, but the bulk are better left in the ground for a time. The best way is to start at one end and prepare the ground for planting next season's crop.

Globe Artichokes.—These ought now to be well protected from frost by placing some protecting material, such as leaves or long strawy litter, round the crowns.

Parsnips.—This crop is better for remaining in the ground and left to the frosts. In the event of hard weather, however, a few roots should be lifted and placed away from the air for convenience.

Onions.—Handle the large bulbs as little as possible, but see that these and the rest of the crop do not suffer through any decay.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Hollyhocks.—It is a mistake to destroy these annually after flowering, for though usually treated as biennials, plants live for many years and form very handsome specimens. My plan after cutting over the old flowering stems is to place a few spadefuls of soil around each plant as a winter protection.

Humea elegans.—Do not err in placing plants of this elegant flower in a heated house. It is nearly hardy, and, if kept free from frost, the less artificial heat it receives the better. The plants will ask for the minimum of water at the root under these conditions, but it must not be forgotten that dryness at the root is almost certain to result in the death of the plants.

Spanish Irises.—This is a proper time to plant bulbs of these. They are apt to die out, but this seems to be a result of under-feeding. Most bulbous plants esteem a rich soil, and these especially so; therefore see that the ground is properly prepared before planting. Old clumps or beds should be surface-dressed with Mushroom-bed manure, pigeon or poultry manure and soot, mixed together in about equal proportions, applying it 1 inch thick.

Tulips.—These also should be planted without further delay in ground deeply enriched with rotted manure, and a surface-dressing similar to that just noted spread over the surface. Pheasants and rats are so fond of the roots that it is hardly possible to grow Tulips where these are abundant. Wire-netting of 1½-inch mesh laid above the bulbs and 2 inches below the surface is perhaps the best means of circumventing both.

Helleborus.—At the time of writing, two species are in flower, viz., *H. altifolius* and the sweet-scented greenish yellow *H. odoratus*. Through the winter these will be followed by others. Those

named and the niger section are splendid for cutting, but the flowers should be gathered young or not fully expanded, when their lasting qualities are improved. It is a great mistake to interfere with the plants at this period beyond removing foliage that is unsightly.

Lawns.—All foliage of deciduous trees and shrubs will have fallen by this time unless it be Oaks, and, if so, the grass should be cleanly swept, and any long grass that has escaped notice earlier in the year be cut close under the shrubs. If any planting of bulbs remains to be done on the outskirts of lawns, it should be completed. Limes are apt to throw suckers from the base. These I make a practice of removing while still soft. In any case they should not be left over the winter, but trimmed quite close to the bark, discolouring the cuts with moist clay afterwards.

The Plant-Houses.

Watering.—In greenhouses the greatest care ought to be taken not to spill water on the pathways, and by carefully estimating the quantity of water required to moisten the soil in the pots, none need fall from them on to the stages. The successful plantsman at all times applies water on this principle, but now it is essential for all. Crotons and many other plants which have finished growth will ask for very little water at the root. If syringed, that will be sufficient for days; but if the temperature is kept very low, syringing must be discontinued.

House Plants.—In living apartments these will need frequent watering, usually every day, a simple plan being to keep the saucers supplied with water. Change the plants at short intervals, not only on account of a change being appreciated, but also because most plants do not suffer from a brief period in the usually deadly conditions for plants that prevail in houses, and are therefore available for use after a time in the greenhouses. *Aspidistras*, *Pandanuses*, *Dracenas*, *Aralias* and the more hardy Palms that can be left a long time should be regularly rubbed with a dry cloth to remove dust.

Greenhouse Climbers.—Such things as *Kennedias* and *Lapagerias* are apt to become overthick with growths and entangled, and may now be seen to, the superfluous and obnoxious shoots removed and those preserved neatly tied in, washing such as require cleansing before doing so. It is a never-ending recommendation to remove weakly growths from all kinds of climbing plants, the unobservant never arriving at a knowledge of their utility.

The Kitchen Garden.

Mushrooms.—If a fresh bed is ready for spawning, it ought to be ready for Christmas, or a bed made up now might be in time, or at least for the New Year. Be very careful in the application of heat. Fresh air is essential to the sweetening of the Mushroom-house, and moisture must not be forgotten as a means of securing the proper conditions.

Celery.—Finish earthing-up the latest trenches, forming the soil into a sharp slope and making it as firm as possible to prevent it retaining wet as far as may be. We had an attack of rust in August, and have been applying flowers of sulphur ever since. White sorts escaped, but some reds were very much affected.

The Fruit Garden.

Peaches.—Young trees may be lifted with a good ball of soil attached, the longer roots to be shortened and the trees replanted without delay, adding some loam and making the looser soil firm. Young Apricots and Plums may be treated in the same way, the latter usually making shoots much too gross if not lifted and replanted in this manner.

Planting.—Nursery trees as received should be planted with the least possible delay, the practice of laying in the trees for a more convenient season being one that cannot be commended. While one need not go to the extreme of trimming the damaged roots with an upward slope—a very old practice—do not huddle them close together in a round hole. Spread out the roots 6 inches to 9 inches below the surface, and firm the soil about and above them, finishing with a stake to support the tree from wind-sway. If a mulch is applied, cover it with a little soil to hide the material and to keep birds from spreading it over the border.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

NURSERY NOTES.

MESSRS. GEORGE BUNYARD AND CO., LIMITED, MAIDSTONE.

THIS well-known firm, whose headquarters have been at Maidstone ever since the business was started in 1796, has long been noted as one of the most up-to-date in this country so far as fruit trees and herbaceous plants are concerned. Indeed, trees from the extensive nurseries at Maidstone and Allington must now be finding a home in thousands of gardens, not only in Great Britain, but in all quarters of the globe. At the time of our visit, during the second week in September, we were more concerned with the fruit trees than other subjects, and for that reason wended our way direct to the Allington nurseries, where about one hundred acres are devoted to this branch of the business. Here we found all kinds and all forms of fruit trees, from maidens to trained specimens six or more years old. The soil was ideal and the trees were splendid. During recent years there has been a large demand for pyramid and bush trees on Paradise or other dwarfing stocks, and it was interesting to note that Messrs. Bunyard, to keep well abreast of the times, have a number of extensive and well-cultivated plots devoted to these. Here one can select Apple, Pear or Plum trees of whatever size or age they may require, those which have passed their second year being in a condition to bear fruit as soon as established in their permanent quarters. Standard and half-standard trees, too, were there in great profusion and of all ages, so that those who have orchards or big plantations to make can have trees for almost every kind of soil and situation they may encounter. And the varieties are as numerous as the forms of the trees. Naturally, some sorts are more in demand than others; but after inspecting the extensive stock under the guidance of Mr. E. A. Bunyard we came to the conclusion that it would be very difficult indeed to name a variety which was in any way worthy of cultivation that the firm could not supply.

A dessert Apple of which they are justly proud, owing to the fact that they realised its possibilities before other firms, is Allington Pippin. It is, of course, now well known, thanks largely to the efforts of Messrs. Bunyard. It is a free-cropping variety that does well on nearly any kind of soil, and is of excellent flavour and just the sort for the amateur who has not a lot of space at his disposal. Baumann's Red Reinette is also an excellent Apple for a garden where space is restricted. True, its quality is not so good as that of Cox's Orange Pippin, but it is a pleasant Apple to eat and crops freely nearly every season. A batch of young trees of this variety that we saw were exceedingly beautiful with their heavy crops of brilliant scarlet red fruits. Hitchin Pippin is another good dessert Apple that Messrs. Bunyard think highly of, and rightly so. It may best be described as an early King of the Pippins, being in season at the end of September and during October. The flavour is excellent, the tree has a good habit, crops freely, and the fruits are highly coloured, so that it ought to prove a good market Apple.

Among culinary Apples, Messrs. Bunyard give a high position to Norfolk Beauty, a large, solid Apple that somewhat resembles in appearance Warner's King, except that it has a ring of russet around the stem. Early Victoria is an early

Codlin variety that bids fair to oust Lord Grosvenor from its high pinnacle. It crops equally as freely, the fruits are of grand flavour and larger, so that it has everything in its favour. Hambling's Seedling, although it does not crop very heavily until well established, is also a variety that Mr. Bunyard thinks very highly of. Royal Jubilee, which has found so much favour on the Continent, was introduced by the firm, and we were privileged to see the original tree whence all the stock has sprung. It is now a large specimen, with a trunk nearly a foot in diameter. Although we can only mention these few varieties in passing, it does not mean that there were not others worthy of inclusion. Far from it, because there were all the best recognised sorts in great abundance and in as healthy a condition as one could wish for. Indeed, the absolute cleanliness of the stock, in a season like the present, surprised us very much until Mr. Bunyard explained that every year a certain amount of new farm land is taken in for the young fruit trees, so that a perfectly clean start is assured.

As with Apples, so with Pears, Plums and Cherries. We have already made passing reference to the trained trees of these, and, taken as a whole, we never remember seeing a better lot. Such good varieties of Pears as Beurré Hardy, Louise Bonne of Jersey and Conference were there in their thousands, and the heavy crops many of the young trees were carrying proved that the right system of pruning and training to induce fruitfulness had been adopted. Small fruits, such as Gooseberries, Currants, Raspberries and Strawberries, are all grown in very large quantities, the firm having for many years made a speciality of Strawberries. Nuts, too, for which the county of Kent is world-famed, also find a home in the Allington nursery, and anyone who wishes to secure plants of the genuine Kentish Cobs and Filberts can rest assured that they can be obtained here.

The cultivation of fruit trees, such as Apples, Pears, Plums and Cherries, in pots is now very largely adopted in many gardens, and those who visit the Royal Horticultural Society's autumn shows will know that Messrs. Bunyard are past-masters of the art. Their orchard-house is a lofty, span-roofed structure, and trained up the pillars and along the girders are cordon Pears, these being planted out in the natural soil. At the time of our visit the pot-grown trees, which had been in the house, were accommodated in a skeleton house covered with wire-netting, and some very beautiful examples there were. In growing such fruits in pots a great deal depends upon the judicious selection of the trees at the outset, and, judging by what we saw, we should say that Messrs. Bunyard have an excellent stock of all kinds suitable for the purpose.

When we inspected the Roses, we found the same cleanliness and attention to detail apparent. All the bush sorts in particular were wonderfully good, and we have seldom seen better breadths of such varieties as Lyon, Pharisæe, Caroline Testout and Mme. Abel Chatenay. Many of the standards, which looked exceedingly well, were budded on the rugosa stock, which in the opinion of many is better for a number of purposes than the Briar. Certainly it transplants much more readily and does better on light soils than does the Briar.

In addition to an extensive stock of herbaceous and alpine plants, which are grown in their Maidstone nursery, Messrs. Bunyard have a very fine stock of hard-wooded ornamental trees and shrubs, including Rhododendrons and Azaleas, hardy

Heaths, Daphne Cneorum, Japanese Maples, Tamarisks of various sorts, including the beautiful *avetialis* or *Pallasii* rosea, Hypericums, Berberises, Thorns and numerous kinds of conifers.

The few foregoing notes, brief though they are, may, perhaps, serve to indicate to some extent the extensive business that is carried on by Messrs. George Bunyard and Co. in a county that has long been known as the Garden of England.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

BORDER OF ANNUALS AND ROSES (K. M. K.).—The undue legginess of all the plants is doubtless due to an excess of shade, and in a small enclosed area this would of necessity be enhanced. Certain annuals do not object to partial shade, provided it is not too dense, and Poppies, Larkspurs, Bartonias, Lupines, Asters, Stocks, Snapdragons, Linums, Marigolds and Eschscholtzias are worthy of trial in the circumstances. You could, of course, treat the border entirely as a shady one, and grow Lilies, Primulas, Polyanthus, Violas, Phloxes, Irises and much else that would do quite well. Roses that would be likely to suit your purpose are American Pillar, Hiawatha, Griss an Teplitz, Philadelphia Rambler and Lady Gay, and these could be employed in conjunction with Clematis Jackmanii superba, C. Mrs. G. Jackman and C. Miss Bateman.

INCREASING AUBRIETIAS (E. P.).—You failed in this matter because the method, material chosen and time selected for doing the work were all wrong. Had you, when the plants had finished their flowering, closely cropped them over with scissors or shears, pricked up the soil around, given a light mulch of new soil, and watered and encouraged fresh growth for a few weeks, you would have had no difficulty in increasing your stock of plants. After such a preparatory course of treatment you could have lifted your now reinvigorated plant—you dealt with the other plant during a period of reduced vitality due to flowering—shaken or washed away the soil, and divided it as freely as you wished and with impunity. Such divisions in early September could have been firmly replanted in well-prepared garden soil; there would have been no occasion for potting them off. Moreover, young cuttings or slips would at the same time have been available in plenty, and these torn off with a heel attached and inserted in sandy soil without more ado would have rooted quite freely. In early April, had you curtailed the growth a month previously, the plants could have been lifted and divided with equal success at that season also, though of necessity the season's flowering would have been sacrificed.

CARNATIONS AND SOIL (E. G. Fawcett).—There were no insect pests in the sample of soil submitted, though for Carnations it would be considered too light, and the addition of lime and loam of a stony or heavy nature might to some extent prove helpful. The sunless position, naturally, is not of the best, though we imagine the fault to be due to the plants themselves rather than to the other things named. From what you say of the plants we should imagine that the Carnation maggot is largely responsible for the failure, though that could only be definitely settled by our seeing the afflicted plants. If the plants are of your own raising and from layers, you might put them to a test of hardness or otherwise by potting and framing them for the coming winter, and, if maggot was the cause, an earlier evidence of its effects would be forthcoming. Often following the attacks of this pest, a swelling of the stem—the result of rupture owing to the movement of the maggot—is seen, and at such a time the end is not far off. If you could send a sample of the plant, we could tell you if it is healthy or not. There may be other causes of the failure of which we have no information. Are the plants well rooted when put out? Is the stock an old one, long grown in the garden or locality? If so, these may affect it.

PLANTING PRIMULAS AND IRIS KÆMPFERI (*M. J. R.*).—The first-named, *Primula japonica*, could be put out at once, as by so doing the roots would take hold of the soil before spring, and thus enable the plant to make the best growth in its season. The best time for planting the Iris is early April, when growth and root fibres practically come away together. If planted during late autumn, an indifferent growth often ensues, though to some extent this depends upon soil and surroundings.

ROSE GARDEN.

NAME OF ROSE (*Lady Franklin*).—The Rose is certainly Frau Karl Druschki and not Grand Duc de Luxembourg. This latter should be a rich rosy red, the reverse of the petals brilliant lake. It is a fine Rose for bedding, and a very vigorous bush.

INJURY TO ROSE FOLIAGE (*Barholm*).—The foliage you send is badly affected with red rust or orange fungus. You cannot do much now to check the disease, but we advise you to gather the worst leaves and burn them. In winter remove the surface-soil to a depth of 2 inches or 3 inches and burn it; then in spring, soon after pruning, spray with Bordeaux mixture and repeat it every week.

STANDARD ROSES BLIGHTED (*M. H.*).—The foliage sent is badly affected with orange rust or orange fungus. It has been very bad this year, and it seems to us to be worse upon Roses imported from the Continent. You can do very little now except to remove all the fallen foliage and burn it; then have the surface soil burnt to a depth of 2 inches or 3 inches. Next spring, after pruning, spray with Bordeaux mixture, and continue this at frequent intervals.

SEEDLING ROSES (*E. L. W.*).—It would have been better if you had planted out the little plants in September, but it is too late now. Keep them in a cold frame until April, then plant out. They are very liable to damp off, so it is well to keep them on the dry side. If they are from very choice seed, it would be advisable to keep them in the greenhouse; and if they commence to put out new growths, do not check them, but just keep them gently growing and then plant out in May. Do not prune at all.

FORCING RAMBLER ROSES (*E. N.*).—These beautiful Roses, in order to have them in bloom by May 1, should be placed in a cold frame early in December and pruned at the beginning of the New Year. You must retain as much as possible of the long growths made this summer, but side growths are best cut back to one or two eyes. Start the plants in a temperature of 45° by night and 50° by day, and increase this to 50° by night and 55° by day as growth advances. If they appear to be coming on too fast, you can regulate them by affording top ventilation.

VARIOUS QUERIES (*Kanyaroo*).—The four Roses you name are of quite easy culture. Rayon d'Or should be grown in a bed by itself, as its wonderful daffodil yellow would not blend well with yellows of other shades. Sunburst and Lady Hillingdon would go well together, but Lady Pirrie would blend better with Roses such as Mrs. A. R. Waddell or Arthur R. Goodwin. 2. Aurora would be a good coppers yellow China to plant with Laurette Messimy. Queen Mab is also a nice soft apricot shade. 3. Gottfried Keller is a rather difficult Rose to establish; but if you encourage good young growth by pruning back hard in spring, we think you will find it flourish all right.

PRUNING ROSES BEFORE TRANSPLANTING (*M. M. T.*).—It will not be necessary to cut the Rose back very much at the time of replanting. Just cut away the soft wood and remove all foliage; then in March prune the growths made this year back to three or four eyes from their base. The weeping standards will require little or no pruning in the coming spring, as you say they were cut back hard at the time of planting last year. When they have flowered next summer, you should cut away some of the flowering growths, in order to encourage new growths for the following season's bloom. If you have the chalk well broken up and add some humus, such as leaf-soil, spent Hops, chopped turf, &c., you will be able to grow good vegetables; but on all chalky soils it is well to mulch the surface well with rotted manure or spent Hops during hot weather to conserve the moisture.

ROSES IN CHALKY SOIL (*M. M. T.*).—As there was only about six inches of new soil given last season, we should advise you to replant the Roses in November. Just dig them up and put the roots in a trench, covering them well with soil. They will then be quite all right while the beds are renade. Take out another 9 inches of the chalk; then, when putting in the new soil, add a liberal quantity of cow-manure, and you might work in a little well-rotted manure with the remainder of the soil. This will be much better than digging in manure to the beds as they are. In the fine Rose garden at Downside, Leatherhead, the owner, Alfred Tate, Esq., had to have many hundred tons of chalk removed and replaced with soil before this garden was formed, and the splendid condition of the plants amply repaid him for this great expense.

THE GREENHOUSE.

PARSLEY FERN (*CRYPTOGRAMME CRISPA*) (*Purpurea*).—This plant is quite hardy, and may be grown outside in the Fern border, but should be planted in loose stony ground or between two large stones where it will never get dry. It may also be grown in a pot in a cold frame which is shaded from the sun. Cold greenhouse treatment is also suitable for the Parsley Fern.

THE CULTURE OF TYDÆAS (*L. A. H.*).—Tydæas are a very pretty, free-flowering race of gemmiferous plants. They will continue to bloom throughout the greater part of the year; in the greenhouse during the summer, but in autumn, winter and early spring they succeed best in a warmer structure. A winter temperature of 50° to 55° will suit them well.

ODONTOGLOSSUM CRISPUM (*Anxious*).—The shoot sent would indicate that water has been allowed to collect at the base of the young leaves, and this, owing to the dull, cold weather, would do harm. This may have been from overhead watering or syringing, or even when sponging. You do not say whether you used any insecticide when sponging; if so, it may have caused the damage. While we find traces of thrips, we have not been able to discover any of the insects; hence we conclude that they have all been killed by fumigation.

THE CULTURE OF CUPHEAS (*L. A. H.*).—Cupheas need just about the same treatment as the Heliotrope; that is to say, they winter better in a temperature of 50° to 60° than in a structure from which frost is just excluded. One species—*Cuphea ignea*, or platycentra—is extensively used for summer bedding. It is a bushy plant that bears a great profusion of tubular flowers. It, as well as the others, forms very pretty decorative plants for the greenhouse. They will succeed under the same general treatment as the Heliotrope.

SALVIA PRIDE OF ZURICH (*L. E. G.*).—The plants may be wintered in the greenhouse, taking care not to overwater them. With the return of spring young shoots will be freely pushed out, and when these are about a couple of inches in length they make the best of cuttings. They should be treated just like cuttings of Fuchsias, that is, dibbled into pots of sandy soil, and kept close and shaded in a propagating-case till they are rooted, which will not take long. If the atmosphere is too dry, red spider is apt to attack the leaves in the spring.

BEGONIAS (*H. A. S.*).—It is absolutely impossible to state any definite cause for your Begonias dropping their buds, as you say nothing whatever concerning the conditions under which they are grown, except the size of the pots they are in and the fact that the house is shaded during the greater part of the day. The trouble, however, may be caused in various ways; for instance, the roots may be kept too wet or too dry, or the pots may be full of roots, so that they would be benefited by a little stimulant. An excess of stimulants, too, would have the same effect. If the plants are attacked by thrips or the Begonia mite, many of the flowers will drop before opening. By far the most satisfactory plan would be for you to get some practical person to see your plants and the conditions under which they are grown, as he would then be better able to advise as to their treatment.

BEGONIAS AND GLOXINIAS (*East Anglian*).—As far as can be judged from your letter, there seems no reason why your Begonias and Gloxinias should die off in the way they do. We cannot help thinking that somehow or other the frost has access to them. The stimulant named would have had no injurious effect unless it was used very strong. As you have had such a poor measure of success by keeping the plants in the spare room, we think it would be a good plan to try them during the forthcoming winter in the structure where they have been growing, that is if it is kept quite safe from frost in the winter, with a temperature of 45° to 60° at that season. The minimum of 45° represents, of course, the lowest night temperature. During our years of experience we always shook out the tubers clear of the soil after they became quite dormant, and laid them in trays of fine sandy soil or pure silver sand. If the material got too dry, it was occasionally damped; but this was not necessary in the depth of winter. There is no preservative in which the tubers can be dipped. When the season of growth is ended, the drying off should be gradually carried out.

FRUIT GARDEN.

PEARS DESTROYED BY BIRDS (*A. R.*).—Black rags tied to the tree will often scare away birds. Lines of black thread fastened here and there between the branches is an excellent preventive. Birds, as a rule, will not attack Pears until the time of ripening commences, and it may be that in consequence of the dry and warm April your fruit is ripening earlier this year. The way to find this out is to cut a fruit and examine the seed. If it is quite white, the fruit is not approaching ripeness; but if it is turning brown, this is a sure sign that the ripening process has commenced, and the fruit may be gathered. Rather than let the fruit be wholly destroyed by the birds, we should prefer to gather it at once and store it in a cool room. It will be ripe earlier, no doubt.

APPLE TREES ON GOLD CLAY LAND (*R. P.*).—You do not say whether the land is well drained or not. It would be courting failure to plant Apple trees on such land unless it is well drained. The cheapest way of preparing the soil will be to have it steam-cultivated, breaking it or stirring it to the depth of at least 2 feet, and then throwing up the soil into fairly high ridges, or mounds as you call them, the whole length of the ground for each row of trees. This would help to raise the temperature of the soil as well as drain and aerate it. In planting in soil of this description it will be necessary to select such varieties only as are most likely to succeed, because it would be a fatal mistake to plant weak growers or those inclined to canker in soil of this character, such as Cox's Orange Pippin, Ribston Pippin, Lord Burleigh and many others of good quality, which, however, are known to be weak growers. We suggest the following six sorts on the free stock (Crab): Early dessert Apple, Worcester Pearmain; midseason dessert Apple, Allington

Pippin; late dessert Apple, Barnack Beauty; early cooking Apple, Ecklinville Seedling; midseason cooking Apple, Lord Derby; late cooking Apple, Bramley's Seedling.

MISCELLANEOUS.

INJURY TO ROSE AND VINE LEAVES (*M. E. R.*).—The Rose and Vine leaves were apparently attacked by aphides earlier in the year, and the blackish spots upon them are due to the growth of a fungus on the excrement of the insects. We should advise a thorough cleansing of the house during the winter, and of the trees also, and if the aphides appear again in the spring, immediately fumigate with one or other of the excellent fumigants now on the market.

BLANKET WEED IN PONDS (*Mrs. Hugh Graham*).—You cannot do better than apply sulphate of copper to the water in your pond at the rate of one part to 750,000 or 1,000,000 parts, or you may even use it at the rate of 2oz. to 10,000 gallons of water. Apply the sulphate of copper in a canvas bag, and trail it through the water until dissolved, or mix it in a vessel and syringe it equally over the surface of the water. As the weed will doubtless appear again, it will be necessary to repeat the application at intervals of six weeks. The water should be drained off and the lake cleaned out every two or three years.

POT-BOUND PLANT (*T. H. P.*).—The instructions to which you refer are quite correct. A plant which has been growing in a pot for a long period becomes what is termed "pot-bound," the pot being filled with a dense mass of fibrous roots. While in the pot it can be kept watered and moist, for the water given cannot run away without soaking through the ball. But if that plant is placed in a border and the soil about it is left in a looser condition than the ball, then water is very likely to soak into the loose soil without wetting the ball. The rim of clay mentioned in the note is to keep water on the ball, so that it will slowly sink in, acting in the same way as the rim of a pot. We are interested to learn of your success in the use of leaf-mould for your Camellia and Vines.

GARDEN PATHS (*H.*).—The cheapest form of garden path is gravel, and if of a good binding character, *i.e.*, containing a fair proportion of marl, will bind together with watering and rolling almost like cement. Burnt lias clay, or ballast as it is called in some districts, is good also, but does not bind like the above unless mixed with cement. Frequently good paths are made with ballast and lime, though it is necessary that the lime be thoroughly slacked and mixed before putting down, otherwise it will blow. A good path is also made of cement concrete, first putting in rough material, clinkers, broken bricks and stones to a depth of 6 inches, mingled with cement in the proportion of one to six, and finally giving a 3-inch surface dressing of finer material gauged up at three to one. This, with a sprinkling of red ballast finely screened, would make a perfect path, free of weeds, provided that it be also well drained. Brick rubble alone would not bind, and tarred paths we do not recommend.

EXHIBITING CHRYSANTHEMUMS (*Chitree*).—The wording of the schedule in the class to which you refer is particularly vague, and we are not surprised to find that the members of the committee are in doubt concerning it. Assuming that you have given us an exact copy of the wording, an exhibitor would be able to show an entire plant cut from near the ground-level, provided that plant arose from a single stem. In the Chrysanthemum the "stem" would be the main growth; modifications of it would be "branch" or "spray." In the outdoor or border Chrysanthemum a "stem" may support many branches; hence an exhibitor would be within the strict rendering of the schedule in showing an entire plant as described above. Doubtless this kind of thing was never intended by the committee; but if that body does not know what interpretation is right in the circumstances, what of the exhibitor? From the garden point of view the outdoor Chrysanthemum is a decorative subject, one to be shown naturally as grown, and not as solitary flower-heads, as is usual with the large-flowered varieties. Under the circumstances, we should exhibit an entire plant the produce of a single stem growth, since upon the wording of the schedule there is no limit to the number of sprays or flowers such a stem might carry.

VARIOUS QUERIES (*O. S. B.*).—There is no sign of any disease on the Ferns sent, but the fronds have been eaten by an insect. At the same time, all the injuries are old ones, and the authors of the mischief may be no longer present. We suspect that the trouble is caused by weevils, which carry on their work of destruction under cover of the darkness and hide throughout the day. An investigation by the light of a hull's-eye lantern might reveal some of the enemies, though they drop to the ground and hide very quickly, while, as above stated, as all the wounds are old, they may be no longer there. Caterpillars of some of the smaller moths may be answerable for the damage, in which case Heligbora powder might destroy them; but for the weevils the only cure is to catch them, a difficult matter with such low-growing plants as Ferns, as the insects drop in the ground directly they are disturbed. We cannot understand cuttings of Carnations taken from good varieties producing single flowers, and should think a mistake must have been made somewhere. It may be a case of reversion, or probably an error in cultivation may have had something to do with it, but it is very doubtful. *Spiræa arifolia*, or discolor, which is now considered to be the more correct name, needs practically no pruning, although an occasional thinning of weak and exhausted shoots will be beneficial.

EDITORIAL NOTICES.

Every description of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Hints on Planting Roses.—The National Rose Society have just published a new edition of their little booklet, "Hints on Planting Roses." This has been arranged by a committee of the society, and in the new edition the lists of varieties have been brought thoroughly up to date. Copies can be obtained by non-members from Mr. E. Mawley, Rosebank, Berkhamsted, post free 7d.

Potentilla Gibson's Scarlet.—This glorious Cinquefoil, while not reserving to October or November the best of its brilliant flowering, still furnishes those months with a touch of colouring quite unique. The leafy sprays and gorgeous flowers, too, come from a well-groomed leaf-tuft, which as a setting alone is admirable in the extreme. Of perfect hardihood and free growth, it is worthy of encouragement.

A Dwarf Michaelmas Daisy.—*Aster ptarmicoides* minor compacta is a white-flowered, small and compact-growing form of a well-known plant—a perfect pigmy in its way, if, indeed, a pigmy is to be regarded as perfect. We speak, however, of miniatures in the same sense; hence we presume the application of the term is not here inapt. As to the plant, it is little more than eight inches in height, a quite good front-row subject for the border, or, better still, perhaps, for particular places in the rock garden.

Apples with Numerous Seeds.—As a rule, the number of seeds or pips in an Apple does not exceed ten, but this year quite a lot of fruits have contained as many as sixteen or even more. Mr. F. J. Chittenden, Director of the Royal Horticultural Society's Laboratory at Wisley, in investigating the cause of some Apples not being fertile when pollinated with their own pollen, has found that this abnormal number of seeds is particularly prevalent in the varieties *Frogmore Prolific* and *Duchess' Favourite*. It would be interesting to know if any of our readers have noticed it in other varieties.

Dangers of Plant-collecting.—The dangers that beset those who undertake the collecting of new and beautiful plants from such remote countries as Northern and Western China and Thibet were brought vividly before the notice of the members of the Horticultural Club on Tuesday of last week. In his lecture, which was well illustrated by lantern slides, Mr. Kingdon Ward, who has been plant-collecting in the countries named, and who returns again in January, made it quite clear that the hardships and perils that beset the collector in those wild and unexplored regions are very real indeed. Tropical forests and Arctic mountains, to say nothing of war-loving bandits, are only a few of the difficulties that have to be overcome. When enjoying the beauties of such plants as *Meconopsis integrifolia*, *Primula bulleyana*,

Buddleia variabilis and the hosts of others that have been sent home from the countries named during recent years, we shall do well to remember those men who have carried their lives in their hands to enable us to grow these plants in our gardens.

The Washington Thorn.—Foremost among berried trees or shrubs for winter effect should be included the Washington Thorn, known botanically as *Cratægus cordata*. The shiny leaves still remain green upon the tree, while the coral red fruits hang till long after Christmas. Moreover, this tree is most attractive in its flowering season—that is in May and June. The foliage much resembles that of a Poplar, hence it is sometimes met with under the name of *Cratægus populifolia*.

Thousands of *Lilium longiflorum*.—In **THE GARDEN** for September 21, page 477, a writer referred to the desirable qualities of this Lily and the various uses to which it may be put. Not a word too much can possibly be said in its favour, and an idea of the demand for it, as well as the steps taken to meet that demand, is shown in the fact that more than four hundred thousand bulbs of *Lilium longiflorum*, represented by three or four varieties, were disposed of in a single day at one of the London auction rooms. To such an extent does the retarding process now prevail that it is more than probable that the greater number were purchased to be subjected to this treatment. By this means the silvery trumpets of *L. longiflorum* may be had all the year round.

Experiments with the Burning Bush.—Sir Edward Thorpe, who has been conducting extensive experiments with a view to ascertaining why flowers of *Dictamnus Fraxinella*, or the Burning Bush, should be surrounded by a luminous flash when a lighted match is applied to them, writes at length on the results of his trials in last week's issue of *Country Life*. These he summarises as follows: "I believe the true explanation of the phenomenon of the 'Burning Bush' is as follows: If the flower-stalks, bracts and sepals of *Dictamnus Fraxinella* are examined, however superficially, at the time of inflorescence it will be seen that they are thickly covered with fine glandular hairs, many of which have their base in small protuberant ovoid glands, or pustules, of a dark red colour in the red-flowering species. These glands are more or less filled with an essential oil containing the strongly odiferous principle characteristic of the flower. . . . The hairs are really ducts, and so exceedingly brittle as to be readily broken by the passage over them even of small insects, when the essential oil is immediately forced out through the opening. On bringing a burning match in contact with the stem these fine hairs take fire, the essential oil is ejected, and the flame enlarged in size and rendered more luminous by the combustion of its constituents."

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Beautiful Yet Simple Garden Effect.—In a small villa garden in the Bournemouth district I recently saw a number of plants of *Fatsia japonica* about four feet six inches high. One or two plants of climbing *Nasturtiums* had been trained to the stems, and eventually rambled among the leaves of the *Fatsia* plants. The light foliage of the *Nasturtiums* and the red, orange and yellow flowers thinly disposed among the large leaves of the supporting plants looked really unique and charming, and the *Fatsias* were not damaged in the least. It is surprising how uncommon features, such as the one referred to, attract the eye and add to the beauty of a garden.—G. G.

Two Good Autumn-flowering Roses.—Some of the most-prized Rose blooms I have had recently are from Edward Mawley and Florence Haswell Veitch, the former sent out in 1911 by Messrs. McGredy, and the latter in the same year by Messrs. W. Paul and Son. Blooms from the former were of exceptional size and solidity, the petals very massive, the colour intense and the perfume most agreeable. One bloom I cut lasted quite fresh for a week, and was admired by all who saw it. Blooms of the latter have not the size of the former in breadth of petal, but the petals are especially thick and well placed, making a superb flower of exquisite fragrance. The colour is even more remarkable than in the case of Edward Mawley, being more deeply shaded with black. I would strongly recommend both for a September display.—E. MOLYNEUX, *Swanmore*.

Autumn Effects at Wisley.—Visitors to the Royal Horticultural Society's Garden at Wisley should see a bed of many of the latest plants from Western China. This is to be found in the lower part of the garden, where *Gunneras* and *Bamboos* combine so well. The bed is occupied by many very interesting plants and shrubs, conspicuous therein being a wonderful form of *Berberis Wilsonae*. The specimens of the type recently exhibited in the Royal Horticultural Society's Hall were a mass of soft coral-coloured berries, but the plant at Wisley bears brilliant vermilion berries. Noticeable in the same bed are two specimens of *Lonicera nitida*, with most graceful line foliage, and which earlier in the season, I am informed, produce a pretty pink blossom. The autumn tints in the Wisley garden have been very lovely, but conspicuous among the trees and shrubs has been a glorious *Liquidambar*, which has attracted the attention of many visitors.—B. Weybridge.

A Pretty Autumn Combination.—The *Kniphofias* or *Tritomas*, which are also known as Red-hot Pokers, Torch Lilies and Flame Flowers, are bulbous plants of the showiest description, and should be grown wherever a bold and bright effect is desired during September and early in October. At a recent meeting of the Royal Horticultural Society, a *Kniphofia* was staged under the name of Lord Roberts by Messrs. Veitch of Chelsea, but it was considered to be synonymous with John Benary, and as such received an award of merit. It grows from 4 feet to 5 feet high, and the flowers are an intense orange scarlet. This plant has been in commerce for several years, and a pretty combination can be produced by planting this or some other red *Kniphofia* among *Artemisia lactiflora*, which produces terminal

panicles of milk white flowers, small individually, but very showy collectively. The *Yuccas*, with their branching spikes of white flowers, are also suitable associates for *K. John Benary*, while a group of the well-known *Pampas Grass* would also be improved with a few Red-hot Pokers intermixed.—S. T.

A Beautiful-leaved Shrub.—I have never seen *Cercidiphyllum japonicum* commence to colour so early as it did this year, nor have I ever seen it so lovely. I enclose some small tips of branches for you to see how beautiful it is with us. We have a dozen plants, some of them quite 5 feet in height and almost as much through. It would be most disappointing to find it was not quite hardy. The winter frost has not hurt it during the past three years, but it was rather badly nipped in April this year. The plants have made good growth this summer. I think it will prove to be quite as hardy as the Japanese Maples.—F. TUSTIN, *The Gardens, Abbotswood, Stow-on-the-Wold*.

The Carman Peach.—This Peach is proving to be a strong favourite for home gardens in the Central United States. It seems to thrive on warm, light soils, and to be much less desirable in colder and heavier localities. This probably accounts for the diversity of opinion expressed regarding the value of the variety. In those places where it succeeds, it is quite commonly regarded as being the most delicious of Peaches for home use. It is one of the North China type, now becoming very popular in the United States, and is quite distinct in many ways from the types of Peaches earlier known in this country and in Europe. It is a white-fleshed Peach, but colours a bright and beautiful red on the outside when properly grown. There is still a prejudice in many quarters in favour of yellow-fleshed Peaches, but those who are really acquainted with good fruit are generally of the opinion that white-fleshed sorts like Carman are really of superior flavour. This variety originated in Texas with Mr. J. W. Stuberrauch.—F. A. WAUGH, *Massachusetts, U.S.A.*

The Best Culinary Peas in 1912.—This has not been an ideal Pea season, and only a few varieties have done really well. The Pilot as a first early is always reliable here, and this season it was quite up to the average. Early Bountiful, although quite good, gave a lighter crop than usual, but the pods were decidedly larger than ever before. As a second early I again found Senator quite first-rate. Indeed, I never previously saw this valuable Pea give a larger yield, the crop being immense and the pods very large for this variety. This fine Pea ought to be much more widely grown than it seems to be. Carter's Daisy, as ever, was first-rate, an excellent Pea in every way, I was greatly pleased with the new dwarf Pea The Lincoln, raised by Messrs. T. H. Lincoln and Co. of Boston, Lincolnshire. Sown at the same time as Daisy, it came into use quite a week earlier, and gave a very heavy crop of well-flavoured Peas. The pods were packed with large seeds, averaging nine or ten to the pod. Dark green in colour, the haulm with me grew about two and a-half feet to three feet high. This must prove a valuable market Pea. Glory of Devon gave a fairly good crop, but not quite up to former years; Quite Content bore a good crop, but on my strong ground and with the wet, stormy weather it grew to a height of about ten feet, and the stakes only being about seven feet high, the haulm "knead" over and rather spoilt the return. Carter's Harvestman gave a good crop of excellent Peas. Royal Salute was again one of the very best main crop or late Peas. The Gladstone

was not up to the average for the first time in ten years.—C. BLAIR, *Preston House Gardens, Linnithgow*.

Roses in Holland.—Late Roses have not excelled those of last year, owing to the early frosts, and practically all plants growing in exposed situations are over for the year. In more sheltered positions the one that stands apart from all others is the old and lovely La France. Captain Christy looked promising before the cold became so intense, and with milder weather may find a late crop yet. Some varieties have been a little disappointing, and one especially so is Jonkheer J. L. Mock. It suffered badly from mildew after the first flowering, and has been unsightly ever since, in spite of attention. Can you give me the origin of a Rose named *Amabilis*? It is a Tea of a rather undefinable pink colour, of no special merit, and is, to its disadvantage, a weak grower. Many Roses ripened off very early, one in particular being Lyon. It has had no leaves for a month worth speaking of, also Augustine Guinoisseau. Zephyrine Drouhin finds more favour every year, and grows more and more indispensable, as also do Rose d'Evian and Johanna Sebus. General Macarthur has had a good season, having no equal in its special colour.—H. RABJOHN, *Twickel, Holland*. [There were two Roses named *Amabilis*, both Tea-scented. One was raised by Touvais in 1857 and the other by Robert. They were, presumably, chance seedlings, as no mention is made of their parentage, and, as you say, they are of no special merit.—ED.]

Saxifraga burseriana "tridentata."—The appearance by now of this ridiculous name in so many catalogues makes it necessary to point out the error. *S. burseriana* can do many things in the way of beauty; by no possible chance could it ever become in any way tridentate, or it would be *burseriana* no longer. The unlucky name arises from the fact that Herr Sundermann (I fancy) originally sent out under the very proper varietal name of *S. b. tridentata* that distinct and magnificent large-growing, large-flowered form of *S. burseriana* which alone prevails in the deep valleys of the Southern or Tridentine Dolomites, and from which major, Gloria and magna have each in time emerged. Tridentine being an adjective better known to ecclesiastical students of the Tridentine Council, or Council of Trent, than to most gardeners, it was not unnatural that laymen should fail to recognise the varietal name as meaning simply "belonging to the district of Trent," and, having received a name that had no sense in their minds, proceeded to distribute the great *burseriana* form under a new name that has no sense in anybody's. *S. b. tridentata* is merely the prevailing form of the Trentino, or County of Trent, or Tridentine Alps; and, as by far (with its sub-varieties) the finest form known of the species and the richest in growth and flower, should also be the prevailing form in all our gardens. I will only add that in the Tridentine valleys I have never seen yet any variations from this ample and magnified form, so different from the compact little *burserianas* of the Northern ranges and of higher altitudes. For, to the confusion of those who look on *S. burseriana* as a high alpine, or have seen it shrinking into tight masses on the crests of the Karawanken, one (at least) of its most brilliant and characteristic Tridentine stations is barely seven hundred feet above the level of the Adriatic, full in the vineland that makes the valley of the Adige such a scented Paradise in June.—REGINALD FARRER.

The Century Plant at Kew.—An illustration of this interesting plant in an earlier stage of its development appeared in *THE GARDEN* for May 25, and a comparison with this specimen as it appeared then and as it appears to-day is not without interest. At the earlier date the flowering spike resembled a gigantic Asparagus shoot, and the huge rosette of foliage was thick, succulent and rigid. To-day the immense rosette of foliage is but a ghost of its former self. The bold step that this plant has taken in producing flowers and seed is a final one. The whole energy of the plant is centred on its reproduction, marking the close of the history of this stately specimen. The leaves, now limp and drooping, have expended their latent store of nourishment on the production of an immense inflorescence bearing flowers and seed, and the life's work of the plant is nearing completion. The specimen under notice is that of *Agave atrovirens*, a native of Mexico. The branching inflorescence is about twenty-five feet in height, and the age of the plant is probably about seventy years, although, like other Agaves, it is known as the Century Plant from the fallacious supposition that it flowers once in a hundred years.

Exhibits from School Gardens.—In "Notes of the Week," issue November 2, the reference to exhibits from school gardens is very timely. Such exhibits have been staged at a number of shows lately. At a recent exhibition near Poole, Dorset, there was a very fine lot of vegetables staged which had been grown by a number of boys in the neighbourhood. These exhibits were very highly commended by the judges. Some years ago I gave practical lessons to about forty schoolboys in the Master's garden, and it was astonishing how well they succeeded in growing good crops. Readers may realise it to some extent when I say that His Majesty's Inspector of Schools recommended that the highest Government grant be given to horticulture at that school. If societies were to provide classes for children, such as the Bournemouth one does, great progress would be made by the children in the work of horticulture.—G. G.

FORTHCOMING EVENTS.

November 18.—National Chrysanthemum Society's Executive Committee Meeting.

November 19.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster. Lecture by Dr. Hamilton, F.R.G.S., on "Some Gardens In and Around Bournemouth." Norwich Chrysanthemum Show (three days).

November 20.—National Chrysanthemum Society's Exhibition and Conference at Essex Hall. Newcastle Chrysanthemum Show (two days). North of England Horticultural Society's Meeting at Hull (two days).

November 21.—Norfolk and Norwich Show (three days). Aylesbury Chrysanthemum Show.

November 22.—Chrysanthemum Shows at Aberdeen (two days), Dunfermline (two days); and East of Fife Chrysanthemum Society's Show (two days).

THE FRUIT GARDEN.

HOW TO COMBAT AMERICAN GOOSEBERRY MILDEW.

SO rapid has been the spread of this very virulent disease among the plantations of Gooseberry-growers, private and commercial, during the last two years that it is greatly to be feared there are few who are unacquainted with it. It may be helpful to some if in this article possible methods of attacking the disease and holding it

summer stage, violently infectious by reason of the multiplicity of spores produced, but fairly easily attacked by spraying with fungicides. It is also pretty well known that later the felt-like white mycelium on the shoots turns a brown colour, due to the formation of the winter spores. These do not spread infection at the immediate time; but they are a more serious trouble, since it is by means of these winter spores that the fungus is carried over the dormant season. They are provided with a hard, outer shell or skin, and at present no fungicide is to be found which will corrode this skin without at the same time doing damage to the bush.

The spores fall to the ground during the winter, and it is from these that fresh infection is set up in the spring, when the wood is young and tender and susceptible to injury. It is because the winter spores fall off during the winter that the Board of Agriculture insist on the pruning of affected bushes being completed early in the winter, and also that all prunings should be collected and burnt. If this work is thoroughly carried out now, there is reasonable hope that the disease can be checked considerably; but, of course, if it is left till after Christmas, there is but little hope. It is a good plan, where there is only a little disease, to have the affected shoots pruned off first, put in a pail, which is kept well dressed with paraffin, and at once taken and burnt without waiting to complete the ordinary pruning of the bushes. When this latter is done, it will be possible to see any pieces of disease which may have escaped the eye at the first operation, and these can then be served in a similar way.

When the disease first appeared in this country, the Inspectors of the Board of Agriculture recommended, if they did not order, that the tips of shoots affected with the disease in its summer stage should be removed at once. As this was generally the time when growth was most active, shoots so pruned often shot again at several buds, and the resulting growth was frequently affected with the mildew, so that the only result of this treatment was to increase the amount of infection on each bush. They do not now recommend this summer tipping; but it is always open to a grower to adopt it when he thinks there is little or no danger of the pruned shoots breaking into growth. If it is possible safely to remove the tips when only the summer stage is present, the amount of infection can

often be substantially reduced, while the winter pruning work is also sensibly lessened.

Another course of action to be taken in combating the mildew is by means of spraying, and this can be done in two ways—by strong winter washing with copper sulphate, 6lb. to 100 gallons of water, when the bushes are dormant, or by more diluted summer sprays when growth is active. For this latter there are several mixtures which can be used: Liver of sulphur, half an ounce to 1 gallon of water; Bordeaux mixture, preferably in the form of paste, 1lb. to 10 gallons of water; and,

THE CENTURY PLANT (*AGAVE ATROVIRENS*) FLOWERING AT KEW.

in check are outlined. There is grave reason for believing that this is, unfortunately, all that can be accomplished, and that it is not possible to stamp out the disease, but only to check its ravages and keep it somewhat within bounds.

It is not necessary to give a long, detailed description of the fungus, or to capitulate at length the various changes it undergoes in a season. Most growers know and can recognise the white, felt-like mycelium which attacks the growing tips of the shoots and the under side of the leaves on such tips during May and June. This is the

lastly, the new lime-sulphur. This last spray must be used with great caution, as it is very liable to damage the trees, completely defoliating them in some cases.

Professor Salmon of Wye College is responsible for this new treatment, and he stated a few days ago that, as far as he knew at present, it must be considered unsafe to spray Berry's Kent and Yellow Rough with lime-sulphur, that at the standard summer strength (1:01) Warrington and Whinham's were quite unhurt, while Lancashire Lad could be safely sprayed with half summer strength (1:005). As he has found trees thoroughly sprayed with this mixture

ROCK AND WATER GARDEN.

A GRECIAN WOODRUFF.

(*ASPERULA SUBEROSA*.)

THIS beautiful little Grecian plant is quite one of the most charming plants to be seen in the rock garden during the months of May and June. It is at its best at this period, although flowers are produced throughout the later summer months as well. Grown singly, the plants present the appearance of hoary, woolly tufts surmounted by numerous pretty

rain. The glass should be placed in position in early winter, and kept on till about the end of March. Both make charming plants for growing in pans for the alpine-house. They are easily increased by means of cuttings in summer, using very sandy soil and placing the pots in a close frame, or by division in the early spring. W. I.

ROCK GARDENS IN THE MAKING.

(Continued from page 564.)

Artificial Rocks.—While having not the least sympathy with, and no desire to encourage, the use of any combination of materials which might be grouped under this head, it has to be admitted that occasionally amateurs get a fair amount, both of pleasure and success, from the use of them. In past days a not infrequent thing in a garden—nursery or private—was the "wilderness"—my grandfather had one such—while variations or modifications of it were known as "grottoes," which, with their massed arrangement of shells, were more interesting to the conchologist than to the gardener; and that worst of all types, because of a hideousness and inutility better imagined than described, which one may not inaptly refer to as "crockeries," by reason of their make-up and for lack of a more descriptive term. Happily, however, these things savour of the past, the only remaining relic our gardens contain of such atrocities being the clinkered burr of the brickfields, exposed to view unblushingly in all its crudity and nakedness, or veiled by a curtain of cement, as though the very sight of these incongruous piles was intolerable to the builder himself. It is, we have been told, an attempt to imitate Nature; but we have yet to be told that the attempt was succeeded by success.

THE GRECIAN WOODRUFF (*ASPERULA SUBEROSA*) IN THE ROCK GARDEN.

quite immune to the disease, while those unsprayed on each side were very badly affected, it is evident that there is some ground for hope that lime-sulphur may be extremely useful in combating the mildew, particularly if the scientists can overcome the liability to damage certain varieties.

There is yet another method which is being tried, that is, the application of finely-ground sulphate of iron to the ground around the bushes to destroy the winter spores which may fall, or, if this is not possible, to attack the minute growths when they germinate in the spring. Two applications should be given, one after pruning is finished, before the ground is dug, and another in the spring, before the first hoeing takes place. About one and a-half ounces to the square yard should be sufficient at each application if the crystals are very finely ground and the distribution is thoroughly and evenly carried out. It is only necessary to spread this as far as the boughs reach, and not all over the ground.

By a judicious and careful use of any or all of these various methods it is possible to keep the nasty disease within bounds, though none of them at present can be said to be capable of entirely stamping it out.

Brentwood, Essex.

F. HAMMOND.

pink flowers. But in time the tufts grow together and form a hoary carpet, as seen in the illustration, covered with flowers, a very attractive plant worthy of a place in the most select garden. *A. suberosa* is one of the choicest members of this family, of which perhaps the best known is the Woodruff (*A. odorata*), a great favourite in many gardens for planting in shrubberies or Fern borders, where it can run about without restraint. Another choice little species is the Pyrenean *A. hirta*, which also makes a carpet. It is rather taller than the Grecian plant, with paler pink flowers produced during the same period. Our native Squinancy-wort (*A. cynanchica*), which is found on the chalky downs, is also worth a place, for it has a neat, prostrate habit, with numerous pale pink flowers. Of the annual members of this genus, the best is *A. azurea* from Syria, with blue flowers on branching stems about one foot in height.

The cultivation of *A. suberosa* and *A. hirta* presents no difficulty. They prefer a warm, sunny position and to be planted in very gritty, well-drained soil. A ledge well up to the level of the eye is the best place, for then it can be seen to advantage. For *A. suberosa*, which, owing to its woolly foliage, suffers somewhat from damp in winter, it is necessary to have a piece of glass raised just above the plant to throw off the

The most I can say in its favour is that it appeared ingenious. The least I can say against it is that it has ever proved a delusion and a snare.

The Least Bad.—If my choice laid between these two, I should unhesitatingly declare in favour of the ungarnished, uncemented article, for no other reason than that all its shortcomings are on view, hence do not mislead the gardener. Moreover, crack and cranny and crevice—assets of inconceivable value even in the best-arranged rock gardens—are all retained and available for treatment. In the cemented, made-up form this is not usually so; hence one of the greatest sources of decorative planting—that which above all others not merely embellishes but effaces rock—is dried up. In all probability this make-believe kind of rock gardening has had its day, and in its stead is springing into being a type far more beautiful and valuable—particularly so from the utilitarian standpoint—than such incongruities could ever be. Moreover, and so far as I have observed, these great artificial erections perform no function of which the natural rock is not capable, nor are they to be recommended from an economical point of view. On the other hand, I am tolerating for the moment the untold crudities of the uncemented clinkered burr for the sake of those who

consider themselves surpassingly rich with a few barrowfuls of such things, and because of the difficulty of obtaining stone in small quantities in town or suburban districts. These, too, are tolerated for their pleasure-affording attributes by that rather large group of amateurs who to-day do their rock gardening in the space of a few feet. To such as these they are invaluable, and they have their own ideas of making them a success.

Where Failures Occur in the use of such things is more frequently the outcome of the cramped pocket arrangement—it too often constitutes a sort of water-tight compartment—of a few inches deep, out of touch with everything save for the small parcel of soil the pocket itself contains. For the amateur is not content to use cement to hold the erection together; he takes considerable pains to ensure that the roots of the plants do not escape from their allotted holding. All this is, of course, wrong, immeasurably so, and when we remember the liberty-affording crevices of natural rock it is a matter for surprise that the plants exist at all. Some plants, however, are capable of an existence even on the driest wall-top, and these and their sturdiest kinsmen are those best calculated to endure.

How Alpine Plants Root.—This phase of the subject is so intimately interwoven with the question of suitable and unsuitable rocks that a few remarks *à propos* at this juncture will not be out of place. Reference has already been made as to the value of crack and cranny and crevice, and if we imitate Nature at all, no matter how feebly, we must do so in this. Not a few alpine plants send their root-fibres down to almost incredible depths in their native habitats, the crevice itself being a larder filled with the choicest foods. Thus a splendid tuft may appear to exist on the merest ledge of rock, though its root-fibres meanwhile may be in a deep crevice yards away. In the great rock garden at Friar Park this phase of the subject has been fully appreciated, and whether the rocks be of huge proportions or of quite ordinary size, the packing of crevices with material of suitable description ever receives studious care. Hence, as a result, is there so much of that "art which doth mend Nature." In like manner, just as the Friar Park example endeavours to imitate Nature, so might the builder of even the smallest rock garden do in this particular, viz., the forming of crevice or cranny for the reception of certain classes of plants. Quite a large number of plants do well enough and grow into free-flowering masses when planted in the ordinary way, though there are others—and they constitute a by no means inconsiderable number—that are best otherwise—best because of the improved possibilities for their natural display, best as an aid to their longevity and comparative immunity from slugs, and not least because Nature apparently intended for her richest jewels a setting apart from the rest.

E. H. JENKINS.

(To be continued)

IRIS KÄMPFERI.
(*SYN. I. LÆVIGATA.*)

THE illustration that accompanies these notes will afford some idea of one of the many beauties that are to be seen at the Wisley Gardens of the Royal Horticultural Society. This Iris thrives remarkably well there, and the success achieved indicates in some degree its requirements. To start with the soil, this is not in any sense of a heavy or retentive character; hence it is quite at home near to, and frequently in direct touch with, the water, but slightly raised in most instances above the average level of the pools. This fact should not mislead intending planters into thinking that the same treatment will suit in every instance. If planted, say, in a heavy loam with a tendency to clay, the surrounding soil being possibly to some extent water-logged, it will be much safer to keep the plants somewhat higher out of or above the water, and do what is most essential in our opinion—provide for drainage prior to planting, so that the water passes away from the roots. With this Iris, as with many other plants, it is a question of soil and water in combination more than anything else. A cold, stagnant soil is most harmful. This Iris cannot tolerate such a state. Warmth is most essential; this it gets at Wisley in the

NEW USES FOR LIME IN THE GARDEN.

MODERN science has been busy with liming experiments during recent years, and has now shown that lime has functions to perform which are out of the run of those usually and formerly associated with it. Nitrification, for example, has been found to require an alkaline condition, and it is probably largely due to lime that this has been brought about when sulphate of ammonia has rendered the ground absolutely poisonous to plants through acidity. Another and more interesting development in the use of lime of late years has been in the direction of finding out what plants are specially benefited by its use, or even injured, for the latter has been found to be the case with several plants, strange though it may sound. A notable instance of this has long been known in Spurrey, which increases where the lime goes out of the ground, and the same antipathy has been found by experiment with Sorrel, Serradella and blue Lupine, again, have been found to be injured by liming, in the case of Lupine after each of three successive experiments. Gladioli, also, and Red-top have been injuriously

IRIS KÄMPFERI AND WATER LILIES IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT WISLEY.

sunny positions the plants occupy. So it is at Clandon Park—the Earl of Onslow's—where they thrive splendidly by the margins of the lake, but in sunny, warm situations. In Japan these Irises are grown on low-lying ground, where, when needed in the hot weather of that part of Japan, they can be irrigated as occasion may arise; but this is far different from growing them in this country only slightly above the water-level. It is a great pity that this lovely Iris is not grown more than it is. It is a sun-loving plant, and one that delights in an abundance of water during growth, but the soil should be sweet and porous, all the same. ANGLO-JAP.

affected. More useful, perhaps, are the experiments on Grasses which have been made in America, which indicate that the needs of these plants are not all similar, even the commoner sorts showing a difference, though the results are only the fruits of two years' experience. Timothy, Awlless Brome Grass, Smooth Meadow Grass and others may, it seems, be benefited by liming, and in various degrees; but Sweet Vernal, Soft Grass and an American variety show less benefit or none at all. Indications, in fact, suggest the probability that individual Grasses show just as great an inclination or aversion to liming as do those of leguminous

plants, Melon and other families which have been experimented on.

Water Melons, for example, showed distinct injury from liming, the second year more than the first; while, on the other hand, the Musk Melon would only flourish where the lime was. In the same way garden vegetables have varying capacities for appreciating lime, and none of those experimented with, which included most of the common vegetables, as well as Dandelions, showed a dislike to liming, though the benefit was not at first apparent in one or two cases. A multitude of good effects on plant-life and soil fertility are now, in fact, found to be due to lime, which might almost be termed the universal solvent of the soil.

GERVAISE TURNBULL.

THE GREENHOUSE.

A NEW PERPETUAL-FLOWERING CARNATION

ROSETTE is the name given to a new and beautiful Perpetual-flowering Carnation with rosy cerise flowers. The newcomer is of good constitution and blooms freely. The flowers are illustrated as grown, having been photographed from a plant in a $1\frac{1}{2}$ -inch pot shown by Messrs. Stuart Low and Co., Bush Hill Park, Enfield, at a recent meeting of the Royal Horticultural Society. The flowers are refined and of perfect form, and, above all, the calyx is sound. Rosette is bound to become a general favourite as soon as its many virtues are known.

STOCKS FOR THE GREENHOUSE.

Stocks grown in pots for flowering in the greenhouse in springtime are more appreciated every year. The experienced cultivators know which plants to retain and which to discard when aiming at the production of a majority of double flowers on strong stems. The inexperienced growers do not, and therefore they generally select the strongest plants possessing long, green leaves, and throw away, what appears to them, to be the poorest plants. Those specimens most likely to bear double flowers possess rather short, rounded leaves of a blue-green colour, and are not as gross-growing as the others. They are quite as strong, really, as the stems are thicker and shorter-jointed, the central spike being, as a rule, a strong one and the side branches short, bearing from three to five or seven double flowers. Well-grown plants of the intermediate section bearing single flowers are lovely, fragrant and effective at a season when such flowers are scarce.

The plants should be placed under glass before the end of November. They are best when grown under cool conditions while very young, as any attempt at forcing them only weakens the plants. When the really cold weather, with occasional

frosts, comes, the plants are best placed in a greenhouse from which damp and frost can be excluded. Keep them near the glass on a stage or shelf away from the hot-water pipes. Give water carefully, never allowing the soil and roots to get dry nor keeping it and the roots in a saturated condition. Feeding should not commence until early in February.

G. G.

HOW TO PRUNE PLUMBAGOES.

The Plumbago is one of the best of climbers for an amateur to train under the glass roof of his greenhouse or conservatory. Directly the flowers have faded and many basal leaves have also

CARNATION ROSETTE. A REFINED PERPETUAL-FLOWERING VARIETY.

shrivelled on the current year's shoots, some pruning must be done. It is a mistake to prune hard back at this time. Leave about nine inches of stem, and then prune to within 1 inch of the base about Christmas-time or early in January. So treated a check is not given to the plant, and the basal buds swell up nicely.

When the first pruning is done, lessen the quantity of water at the roots considerably, and from the middle of December to the first week in February cease watering altogether. At the latter period give a thorough soaking after clearing away any loose surface-soil and then apply a top-dressing of lumpy loam, leaf-soil, rotted manure and sand. SHAMROCK.

THE FLOWER GARDEN.

SOME GOOD CHEAP TULIPS.

READERS may remember an excellent picture of the double Tulip Murillo in the September Bulb Number of THE GARDEN, and that the writer of the note which was published with it seemed very surprised—it evidently had been given him along with some others—to find for how small a sum such a treasure could be bought. He thereupon made an appeal to me to furnish a list of some of the best varieties that may be purchased at a correspondingly low figure. I have no difficulty in responding to his invitation, for although the writer above mentioned almost seemed to think that it might be so, neither the beauty nor the utility of a Tulip can be gauged by its price. Undoubtedly in the early days of their introduction, or upon their discovery by the flower-loving public, varieties such as Clara Butt and Le Rêve (yclept of old, Hobbema) command fairly high prices for some little time, yet their power of increase is such that before very long they get the better of the demand, and then sadly, but necessarily, the dealer marks them down. The few "old stagers" that always remain expensive are those which increase but slowly, such as Chameleon, Zomerschoon, Columbus (French Crown), Ada and Louis XIV.

As the picture of Murillo showed it growing in a garden, I imagine what is wanted from me is a list of cheap varieties that are especially suited for borders or for bedding. For convenience of reference it will be well to take them in the order in which they are usually placed in catalogues; and, furthermore, to carry out the intention of this note I have fixed a shilling a dozen as the limit beyond which I will not go, except in two or three instances, which will be duly noted.

Early Singles.—The varieties selected have longer stems than many, and, to my thinking, have a more taking appearance than the short, stiffer-looking ones. Couleur Cardinal.—I have seen this offered at 1s. per dozen this year, but generally it is about 1s. 6d.; however, so highly do

I think of it that I have not hesitated to include it; deep blood red, outer petals flushed rich plum. Duchess of Parma, orange and crimson, lovely under electric light; Dusart, rich red; Fred Moore, a darker form of the well-known Thomas Moore—goes so well as a dot plant among yellow and orange Polyanthus; Keizerskroon, bright red and yellow, a little "loud" unless carefully placed; Prince de Ligny, a particularly graceful yellow; Prince of Austria, tall red orange, a wonderful luster, and as it becomes more orange with age, almost may be said to give two displays. There are, and have been, great flowers and great fruits. This, surely, is one of the great flowers. Scarlet Mammoth, really

a midseason bloom, a square-shaped flower borne on a medium-lengthed stem and of such intense brightness (red) that one wants blue spectacles to look at a big bed of it in full sunlight; Stanley, a delightful carmine rose; Van Gooyen, a tall Cottage Maid, but oh! such foliage—powdered apple green is a hint of what it is like; Vermilion Brilliant, an early brilliant and very reliable red; White Hawk—sometimes I like White Pottebakker rather better, sometimes White Hawk. This latter is a trite later to bloom, and has somewhat crinkled petals.

Early Doubles.—Murrillo: Under the circumstances it goes without saying this must be included. The accompanying illustration shows a large bed of 500 bulbs as it grew this last April in Mr. Carruthers' garden at Eden Grove, Carlisle. I always say, "Give me a big enough mass of almost any one flower and the effect is good." Very likely this gentleman has filled up this bed already for next year's show; but if not, and if he should want a real bright spot in the spring,

time comes round. Bouton d'Or, a deep yellow that becomes fat and well-looking with age; Didieri alba, a pure white of the lean kind; Fairy Queen, an æsthetic lady in a gown of slaty lavender and canary; gesneriana major (or spathulata), a magnificent crimson with such a base of dark blue; Golden Crown, a dissolving view effect, first yellow, then red; Inglescombe Pink, a pretty delicate lavender pink; Isabella, buff edged, and finally flushed all over rose, a dwarf grower; mauriana, scarlet, with a pure yellow base, late and lasting; Orange Beauty, a massive orange red, also on the late side; Parisian Yellow, a good reliable yellow; Picotee, a graceful plant, white, edged rose; and strangulata, a lovely primrose, rather dwarf (see THE GARDEN for October 19).

Darwins.—Prices rule higher in this section, so I have had to put another sixpence on to my limit of a shilling. The twelve varieties that I have selected are a good representative collection, but to get them I have had to stretch my second limit in the case of Mr. Farncombe Sanders (about 2s. 6d.),

THE ROSE GARDEN.

NOTES ON NEWER ROSES. HYBRID TEAS FOR EXHIBITION.

(Continued from page 568.)

Leslie Holland (Hugh Dickson, 1911).—I do not think the season has suited this Rose. That it is one of the finest Hybrid Teas of its colour we have, anyone who has seen the numerous flowers of it staged throughout the last three or four years by the raisers cannot doubt. It is a good grower, but not vigorous like Hugh Dickson, and should on that account make an excellent Rose for bedding. It is very free-flowering throughout the season, and in this respect will supply a long-felt want, as there is not a really good crimson bedding Rose. Hugh Dickson's habit of sending up long shoots 6 feet or 7 feet high preventing us from calling it an ideal bedding Rose. I well remember the box of twelve staged at the Luton Show, where it was awarded the gold medal, and

A BED OF TULIP MURILLO IN A CARLISLE GARDEN. IT IS A BEAUTIFUL DOUBLE-FLOWERED VARIETY THAT CAN BE BOUGHT CHEAPLY AND PLANTED NOW.

might I suggest a trial of the before-mentioned Scarlet Mammoth as a somersault contrast to the quiet tone of Murrillo. Two other good cheap doubles occur to me—Rubra maxima, a deep red; and Salvator Rosa, a reliable and pleasing semi-double rose and white.

Cottage Tulips.—If we ransack all the catalogues that come to hand, we will find a pretty wide choice of fine things. Most varieties increase quickly and, let the demand be ever so much greater than it is even at present, they will be able to keep pace with it, and we need not fear any huge increase in prices. By the aforesaid process I think I have been able to select what I feel sure all who know them will agree with me in calling a very nice dozen. Before I give the names let me implore the owner of every garden who has a border with a few unfilled spaces still going begging, and who has never grown either Cottage or Darwin Tulips, to give them a trial next spring. A few clumps with, say, six bulbs in each would not be a ruinous matter, and would be much appreciated when flowering

but it is such a distinct and glorious bit of colour that I could not omit it. The first time I ever got among the Darwins in Holland I well remember how this tall variety always stood out from all others in height and brilliance. Baronne de la Tonnaye, a good type of the rose-edged pale pink varieties; Clara Butt, the most popular of all, salmon pink, not so tall or large as many others; Dream, a pretty pinky mauve; Harry Veitch, deep blood red; King Harold, splendid maroon red; Loveliness, clear rose; Mme. Bosboom Toussaint, 156-4 in the Colour Chart, carmine; Margaret, blush pink; Mr. Farncombe Sanders, a grand rosy crimson; Pride of Haarlem, old rose colour, very large flower; White Queen, the nearest approach to a white among the Darwins; and Zanzibar, a most reliable deep maroon, very dark. Tulips are far more accommodating about being planted than Daffodils, and if they are bought at once and planted before the end of November, they are sure to give a good account of themselves.

JOSEPH JACOB.

I have seen it in even better form on other occasions, notably the nine that won first prize at the "National" for any new Rose. All exhibitors I expect have got it, but if they have not they should obtain it, as a good flower of it will attract attention to any box, be it a six, twelve or a twenty-four.

Lieutenant Chaire (Pernet-Ducher, 1910).—The parentage of this Rose does not read very temptingly, Etoile de France not being exactly one of this raiser's "great" Roses; but the Rose under notice has none of the faults of its parent, and with me has been quite a good Rose. I have had flowers of it very much like Hugh Dickson, except that the white line which nearly always appears down the centre of one or more of the outside petals of Hugh Dickson was absent. I believe the other parent was Liberty; in any event, the offspring seems to have missed the bad faults of both of its parents, as it is a better grower than Liberty and a freer flowerer and much better "opener" than Etoile de France. I have only

one plant of it, so cannot write definitely; but I think I can recommend it sufficiently to say, "Try it."

Mabel Drew (Alex. Dickson and Sons, 1911).—This firm's 1911 set I have already referred to. It contains one Tea and ten Hybrid Teas, and of the ten Hybrid Teas I think I should place Mabel Drew on top as the best exhibition Rose of the series. It won the gold medal at the Salisbury Show in 1910. It is difficult to find a fault in this Rose. It keeps its colour well—deep cream—holds its flowers erect, and they are of excellent shape and with fine smooth petals. It is sweetly scented and a good grower, and altogether a Rose that the raisers can justly be proud of. I have seen no mildew on any plants this year, although plants close by had it badly. Certainly one of the best of the new Roses. Strongly recommended.

Margaret (William Paul and Son, 1909).—I am very fond of this Rose. Its delicate colour and shape have always appealed to me since I first saw its blooms at a Royal Horticultural Society's Temple Show some four or five years ago. It is a Killarney-like flower, yet distinct from that variety. Growth and habit good without being vigorous. Free-flowering, and with me nearly exempt from mildew. A good-shaped flower is very telling in the front row, from which remark it will be gathered that there is not much weight about Margaret. She is of the "sweet seventeen" rather than the "fair, fat and forty" stage that appeals to so many.

Miss Cynthia Forde (Hugh Dickson, 1909).—Another Rose that is on the border-line between exhibition and garden. That it has possibilities in the first class is proved by the fact that a bloom of it shown by the raisers secured the silver medal at the last autumn show of the National Rose Society for the best Hybrid Tea in the show. It is a brilliant rose pink in colour, with distinct claims to be reckoned the best flower of its colour for the garden. Very free-flowering throughout the season, good habit of growth, nearly mildew-proof, if not quite, delicately perfumed, altogether one of the best Roses that Messrs. Hugh Dickson have given us. A pink Antoine Rivoire is, I see, a note I made of this Rose when first seen some five years ago in the raisers' nurseries, and that is not praising it too highly. As a bedder I am inclined to put it before Caroline Testout or Lady Ashton. Gold medal at the National Rose Society's autumn show, 1909.

Mrs. Arthur Munt (Alex. Dickson, 1909).—A Rose that I have expected to see more of. It had very bad luck in not obtaining a medal. It is a good reliable flower of ivory white tint, not quite so large as some of the giants, but a delightful Rose in shape and delicately Tea-scented. Nearly mildew-proof, and a good grower without being too vigorous.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Begonia Emita (B. socotrana × B. Pearcei seedling).—A novelty and an acquisition at the same time. It is quite distinct from all other of the B. socotrana crosses, more particularly in colour, which is a great gain. The flowers are large, of pale tawny orange shade, the buds of a deeper shade.

Begonia Optima (B. socotrana × B. single orange scarlet).—This is of clear salmon pink colouring, of a somewhat looser habit of growth than the last. Both were raised and exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

Carnation St. Nicholas.—One of the Perpetual-flowering class, a flower of large size and crimson-scarlet in colour. The variety is apparently of the American type, i.e., with more or less serrated petals, and is endowed with slight perfume. From Messrs. Stuart Low and Co., Enfield.

cushioned centre and short florets of the old type are replaced by a singularly small-cushioned centre and large strap-shaped white florets. These were sent by Messrs. Cragg, Harrison and Cragg, Heston, Middlesex.

Chrysanthemum Mr. Leonard Harrison.—A large single, the florets coloured a reddish crimson, with buff reverse. From Mr. L. F. Harrison, East Grinstead.

Nephrolepis exaltata Willmottæ.—Yet another addition to that remarkable class whose earlier plumose character appears now to be obscured in a moss-like density, a density, too, that has followed on in a sort of consistent graduated order from the beginning. The series constitutes quite a unique chapter in evolution, and should interest the plant physiologist exceedingly. Shown by Messrs. H. B. May and Sons, Edmonton.

Hoheria populnea.—A rare and beautiful New Zealand flowering shrub, having white Deutzia-like flowers in axillary and terminal clusters. The anthers and filaments also are white. The shining leaves are ovate-acuminate, crenately margined, dark, almost olive green, hard and coriaceous to the touch. Not quite hardy except in the warmer west and south-western counties. (See illustration.) From Mary Countess of Ilchester, Abbotshury Castle.

FLOWERING SPRAYS OF HOHERIA POPULNEA, A RARE NEW ZEALAND SHRUB.

NEW ORCHIDS.

The list of new Orchids to gain awards at the exhibition of autumn-blooming Orchids is an exceptionally long one, some of the novelties being uncommonly beautiful and of great value.

FIRST-CLASS CERTIFICATES.

Odontoglossum Aurora, shown by Messrs. J. Veitch and Sons, Chelsea; *Odontodia Bradshawia gattonensis*, from Sir J. Colman, Bart., Gatton Park; *Lælio-Cattleya Orion Othello*, shown by Messrs. Charlesworth and Co., Hayward's Heath; and *Vanda cerulea Lady Holford* and *Cattleya Peetersii Westonbirt* variety, from Lieutenant-Colonel Sir George Holford, K.C.V.O., Tetbury.

AWARDS OF MERIT.

Brasso-Cattleya Hyea and *Cattleya Oberon*, from E. R. Ashton, Esq., Broadlands, Camden

Park, Tunbridge Wells; *Odontoglossum eximium McBean's* variety, exhibited by Messrs. J. and A. McBean, Cooksbridge; *Cypripedium lathamianum* × *insigne Chautinii*, from J. G. Fowler, Esq., Glebelands, South Woodford; *Cattleya Rhoda the Jewel* and *C. Venus Princess*, from Messrs. Charlesworth and Co., Hayward's Heath; *Lælio-Cattleya Walter Gott*, shown by Messrs. Sander and Sons, St. Albans; and *Cypripedium Muriel*, *Cattleya Fabia Gloriosa*, *C. F. Sunset*, *Lælio-Cattleya Golden Fleece* and *Cattleya hardyana La Perle*. These five beautiful novelties were all sent by Lieutenant-Colonel Sir George Holford, K.C.V.O.

Chrysanthemum Queen Mary.—A huge spreading white flower of remarkable proportions. From Messrs. W. Wells and Co., Limited, Merstham.

Chrysanthemum Miss A. E. Roope.—A gloriously rich golden yellow of the Japanese incurved class. A variety of distinction and merit, and handsome withal.

Chrysanthemum Hector Menzies.—A very handsome single yellow-flowered variety of considerable attractiveness. These two were from Messrs. H. J. Jones, Limited, Lewisham.

Chrysanthemum Portia.—A large single-flowered variety of chestnut red colour, the florets having a yellow base.

Chrysanthemum Snow Queen.—A new type of the Anemone-flowered class, in which the huge

the foregoing were shown before the Royal Horticultural Society on November 5, when the awards were made.

GARDENING FOR BEGINNERS.

HOW TO REPOT CATTLEYS.

CATTLEYS, *Lælias*, *Brassavolas* and their numerous hybrids should be repotted when root-action begins, and the best time of all is when a fresh batch of roots are seen pushing from the base of the current year's growth or nearly-developed pseudo-bulb. In Fig. 1 is shown a plant turned out of its pot, and new roots can be seen at the bottom of the last-made growth. A careful watch is advised, so as to carry out the operation before the new roots grow too long; but an observant cultivator will soon be able to just anticipate their appearance and have his plants repotted so that they immediately enter the new compost. Annual disturbance must not be practised, so sufficient space ought to be left for at least two seasons' growth. The object of repotting an Orchid should be to provide additional root room; but this does not always mean that a larger receptacle is necessary. The contrary is occasionally the case, while a pot of the same dimensions is often used. To the novice or beginner this may at first sight appear paradoxical, but when it is explained that a number of the back pseudo-bulbs are useless and must be cut off, the practical idea will at once be grasped. Three or four behind each lead or growing point are ample, and there will be no need to disturb the front portion of the plant to any great extent. One reason in favour of Orchid-growing is that the vitality and flowering capacities of the plants can be re-

tained without their taking up any more stage room, unless the species or variety is worth increasing, when the old bulbs can be repotted, as shown in Fig. 2, to see if they will form a shoot from one of the dormant eyes. There is, however, one other reason for repotting, which occasionally happens in collections where the most skilled men are employed. This is when a plant becomes sick and nearly all its roots decay. The only method to adopt is to wash away all the old soil and dead roots, and place it in a pot just large enough to take the bulbs; but plenty of drainage is essential, while it must be kept firm by a neat, green stick, when, with constant attention, it generally recovers.

Potting Compost.—The most popular rooting medium, and one that will give good results, is as follows: *Osmunda* or *Ar* fibre, good fibrous peat and chopped sphagnum moss in equal parts,

with enough crushed crocks or silver sand to render the whole porous. As each year passes it becomes more difficult to secure peat of suitable quality, and where the best cannot be obtained, *Osmunda* fibre should be chosen instead. Ordinary flower-pots are recommended, which are filled one-fourth of their depth with drainage, over which is arranged a thin layer of sphagnum moss to preserve a free outlet for water. Teakwood baskets and pans with side holes are sometimes associated with Orchid culture; but these are quite out of date, and no successful grower selects them for *Cattleyas* and similar Orchids. When repotting, the

HOW TO PLANT AN APPLE TREE.

THE planting of a fruit tree seems a very easy matter indeed. Make a hole, put in the roots and cover them with soil. Many inexperienced cultivators think this is all that is necessary. The way in which the work is done, however, is the all-important thing. In the first place, the hole should be made quite 6 inches wider all round than the spread of the roots. It must not be made too deep, and the subsoil should be forked up also. If the soil is clayey, the roots of the tree should be nearer the general surface than in the case of a light soil, and be covered with the usual quantity of soil, which will come a little above the surface. This will tend to keep the roots drier and warmer in winter in the clayey loam. Work the soil well in among the roots, make it moderately firm, and duly stake the tree. B.

REPOTTING

LILIUMS.

THE *Liliums* will make moderate growth, even when the bulbs and their roots are retained in small pots, if ordinary care be taken in the application of water and in the cleanliness of the foliage. If, however, the plants are duly repotted, the results are, nearly always, very satisfactory. Of course, the best results are obtained when the bulbs are first potted low in the pots with a view to a future repotting. In all cases this is not done; but where it is not, repotting must be carried out. This work can be attended to now in cases where

the plants are so advanced that roots are beginning to grow from the stems just above the soil. The plants must be potted in a mixture of old fibrous loam, sweet leaf-soil, rotted manure and sand. The loam must be lumpy, but, of course, of convenient size for potting purposes. Press the compost down with the fingers, not with a potting-stick, and provide good drainage. Afterwards water with care, and be sure that the plants are not checked by being kept in too cold a temperature.

The Repotting of Old Bulbs.—Old bulbs that have rested and now show new growth must be repotted in rather small pots. Clear away very carefully the old soil, dead scales and roots, and then pot the bulbs low down in the clean pots. Leave the pots for a time in a cold frame just safe from frost. AVON.

1.—CATTLEYA PLANT READY TO BE DIVIDED AND REPOTTED. NOTE THE LITTLE WHITE ROOTS.

2.—THE SAME PLANT DIVIDED AND REPOTTED INTO TWO POTS OF DIFFERENT SIZES.

last-made pseudo-bulb should be as near the centre as possible, and so arranged that when the operation is completed, the surface of the soil will be on a level with the rim of the receptacle. Press the compost fairly firm and allow the growing point to rest on the top, for it is fatal to cover it to any depth; and when the loose particles are neatly clipped off with a pair of scissors or shears, we get an example similar to the one in the second illustration. A thorough watering is now given to wet the whole of the soil, and if the surroundings are kept moist by occasionally damping the stages and paths, no more will be required for a week or two. As growth advances and root-action increases, water may be applied more frequently till the bulbs are fully matured, when water is needed in less quantities; but the pseudo-bulbs must not be allowed to shrivel through lack of moisture. SENTINEL.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Herbaceous Borders.—When planting a new border it is advisable to stake out the positions where the principal subjects are to be placed, ranging them according to their height and allotting their space according to the habit of the plant. With the large-growing perennials the planting in clumps of three, triangularly, has much to recommend it, as one gets a bolder effect without undue overcrowding. Old clumps should be divided by placing two forks back to each other and pulling apart; this is much to be preferred to chopping with a spade. Select the outer portions, not too large, and plant firmly. Label the plants as the work proceeds, and leave the surface soil level and neat. Give the border a mulching of leaf-mould or spent Mushroom-bed manure.

Echeverias.—These in variety are excellent for edgings to the flower-beds in summer, and the plants must be protected from frost during the winter months. *E. metallica* is almost hardy, and we simply build this up with soil in rows against the wall of a greenhouse, commencing with the largest and sloping towards the top, finishing with the smallest offsets. *E. farinosa* and *E. secunda glauca* are much less hardy, and are best placed thickly in boxes of soil and stood in a cool but frost-proof house.

The Shrubberies.

Tree Pæonies.—The named varieties of these are beautiful objects when in flower, and comprise single and double flowering varieties of almost every shade from white to deepest crimson. When planting, choose a position so that the flowers are not caught by the early sun, as this, when the buds are opening and late spring frosts prevail, is apt to injure them. Enrich the soil with abundance of good farmyard manure, as, where the plants are put, there they ought to remain, for they resent frequent disturbance at the roots.

Japanese Maples.—Several of these, in addition to their charm when unfolding their delicate foliage, are grand in the autumn. When planting, choose well-drained ground and not too heavy in character. These shrubs, like the Pæonies, are apt to get touched with late frosts, so should be planted in a somewhat sheltered place. A variety named *Osaka-suki* turns a brilliant colour.

Berberis Thunbergii.—When planting shrubs, this subject should not be overlooked. Whether on the rock garden or in the shrubberies, it is one of the very earliest to denote the approach of autumn. It will thrive in practically any soil and any position, and a restricted root-run, though stunting growth, only seems to intensify its colouring.

Plants Under Glass.

Mosehosma riparium.—For cool greenhouse decoration at this season a batch of these plants are indispensable, the blush white flowers harmonising with almost any other subject, while the flowers are well suited for button-holes. A few plants, when flowering is over, should be reserved for a supply of cuttings.

Strobilanthes dyerianus.—This plant requires a warm greenhouse to grow it successfully. It is a striking foliage plant, very easily raised from cuttings, and, grown in small pots, is fine for groups or indoor decoration.

Bulbs.—Those placed out of doors under ashes or fibre must be examined occasionally, and those forward enough transferred to cold frames. Before bringing them into the greenhouse well wash the pots.

Cacti.—These will be much better if kept quite dry for a month or two and the structure or surroundings kept as dry as possible. Give a little air to the house on all favourable occasions.

Fruits Under Glass.

Peach Trees.—To maintain a fruitful tree, thin out the growth, doing away with the older wood and retaining as much of the young wood as possible, as it is on this growth that next year's crop will be formed. Lay in the wood as evenly and straightly as possible, and neatly tie it into position. Always endeavour to keep the base well furnished with young wood.

Ventilation.—While fruit trees are dormant, whether Vines, Peaches, Cherries, or other kinds,

they are greatly benefited by an abundance of ventilation, and when there are no other subjects in the same house to be studied, leave the ventilators open day and night, and have a slight circulation of heat in the pipes to prevent any injury from hard frosts.

The Hardy Fruit Garden.

Now that the leaves are all off, any work, such as pruning or planting, need not be delayed. If the positions are not ready for the trees, the latter should be obtained and heeled in, and, if the roots are well protected, they will take no harm. What type of fruit tree to purchase is often a question, but depends upon the position one has to fill in the garden. The pyramid or bush trained is the one usually most suited for small gardens, being very reasonable in price, and if maiden trees are bought, these soon grow into bushy specimens, are easily transplanted, and come into bearing at an early age. If one has a wall, a few cordons will give fine fruit, also if planted on an arch or pergola. The foregoing remarks apply especially to Apples.

The Kitchen Garden.

Celery.—If the weather promises to be frosty, lift a few heads and store where they are easily accessible.

Mustard and Cress.—Seeds should be sown in shallow boxes on fine soil pressed down and well watered with a rosed can, preferably before sowing. Cover with a piece of board or slate to keep quite dark, and stand in a warm house or Mushroom-house. When germinated, remove to the light.

Mushrooms.—If manure is obtainable, continue to collect and prepare for forming successional beds. A little of the shortest straw will do no harm, but the longest should be placed on one side. Keep the temperature of the structure between 55° and 60°. Avoid too much fire-heat and keep a look-out for slugs.

E. BECKETT, V.M.H.
Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Roses.—The planting of nursery Roses should now be proceeded with and finished as soon as possible. For choice, moderately strong plants are to be preferred to either weakly or very strong ones. Sometimes they are planted overdeeply to save staking, but for all the labour involved in steadying each plant with a stout stick, it is not worth while risking its future. Some Fern fronds worked among the shoots will save them from frost-bite.

Carnations.—Those planted out two months ago are now quite established, and if the surfaces of the beds have not been loosened since planting, let them be stirred up now, and any extra strong plants should each be tied to a short stake. Dust the plants and beds thickly with old soot, and see that neither ground nor feathered game can reach them. Those in pots in frames will need no water at the root till about the end of January at the earliest.

Ranunculus.—A portion of the stock may be planted now, being careful in planting not to break the claws. The French is perhaps the most useful section, and also the hardiest. A rather highly-manured, well-worked soil is essential. From 3 inches to 4 inches is deep enough to set the tubers, and they need not be more than 4 inches to 5 inches apart.

The Wild Garden.

Bulbs.—Any additions to be made may be completed at once of Bluebells and the white variety, Solomon's Seal, Dog's-tooth Violets and other common things. The handsomest of all early-flowering bulbous plants is the Crown Imperial, both yellow and red, yet it is very seldom seen. A stock can be raised from home-saved seeds when a few old plants are established.

Foxgloves.—Where these are already established it will be necessary to thin the seedlings to allow those left to strengthen to flower. New plantings may now be made, being very careful not to set the plants in lines. Foxgloves look best with a

backing of shrubs, and suitable positions should be looked out for new plants. The pure white is perhaps the finest form of all.

Climbing Roses.—Advantage should be taken of any rather bare dwarf tree or other suitable object to put in one or more Roses to climb upon it and clothe it with beauty. Queen of the Belgians, Crimson Rambler, The Garland, Elise Robichon and Dorothy Perkins are a few that will succeed. Other Roses worth introducing include varieties of *Rosa rugosa*, *arvensis*, *alpina pyrenaica*, *rubrifolia*, Scotch Roses and Briars. All these are best left alone when once established, the heaps of most of them being as fascinating as the flowers.

The Plant-Houses.

Plumbago rosea.—This is one of the choicest plants at present in flower. Unfortunately, it requires a stove temperature throughout the winter, and, consequently, those who would like to utilise plants for the greenhouse or for decorating apartments should remember they risk losing them. Water copiously with manure-water, and the plants will continue flowering for a long time.

Thysicanthus rutilans.—This is a charming old stove plant which produces very long, drooping sprays of flowers. It flowers at this time and requires hothouse treatment. The clear blue *Eranthemum pulchellum* asks for similar treatment.

Eupatorium micranthum.—Not quite so hardy as *E. riparium*, this is a more useful plant, cut-over specimens being very acceptable at this time of the year onwards. The flowers are gratefully scented and last a long time in a cut state.

Smilax.—Practically hardy, a look-out should be kept for aphid, which is apt to attack the sprays during the winter season. Syringing with warm water strengthened with extract of Quassia, or fumigating with nicotine, is imperative on its first appearance, otherwise the foliage may be spoiled if the aphid is allowed to spread unrestrained. Our stock is grown in narrow borders, and receives no water at the root during the winter.

The Fruit-Houses.

Strawberries.—The pots should now be stored for the winter in cold frames, first cleaning the surfaces of all extraneous matter. Bring the plunging material well over the pots as a means of preserving them from fracture during frost. The frames need never be quite closed unless during intense cold. Mildew sometimes appears on Royal Sovereign, and it may be judicious to dust all the plants with flowers of sulphur as a preventive.

Pruning Vines.—As soon as the foliage drops from Vines cleared of their crop they should be pruned, at the same time cutting away all snags that may not have been removed during summer—the proper time for doing so. If the rods cannot be washed forthwith, examine the borders lest they become over-dry, and if necessary apply a moderate quantity of manure-water.

Young Vines.—Those prepared for planting and now matured should be cut back to the length required. Usually 2 feet in length is sufficient. Store them meanwhile in a cold house where there is no fear of the least excitement to grow at the root. If there are no means of keeping out frost, the pots should be plunged well over the rims in some dry, non-conducting material to preserve the roots in an equable temperature and to keep them from being frozen.

The Vegetable Garden.

Broccoli.—In localities subject to intense frost, the old practice of lifting Broccoli and laying it in with the heads away from the sun, and also covering the exposed stems with earth, is one that can be recommended. A less laborious operation consists in cutting the roots with a spade, the middle of each row being deeply pierced with the tool. Now is the time to employ these simple precautionary means.

Brussels Sprouts.—Some growers remove a large portion of the side leaves, an unnecessary proceeding usually. At the same time, it is a mistake to have broken foliage and leaves that have yellowed naturally left about the quarter. Remove all such, and it may also be necessary to stir the ground about the plants with a fork. Little things such as this have a peculiar effect on the health, vigour and lengthened production of the plants.

R. P. BROTHKROFT.
Tynningham, Prestonkirk, N.B.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Chicory Salad.—To those who find Dandelion rather too sharp, one can strongly recommend Chicory as a winter salad of beautiful appearance and excellent flavour. To produce suitable bleached leaves, the tap-shaped roots are packed closely together in deep boxes with a little soil between. The boxes are placed in some dark, warm, moist position, where the leaves that are so much appreciated will quickly push up. In gardens where a demand already exists, there will be an ample supply of roots from seeds sown in the spring; but, failing that, it will not be either difficult or expensive to purchase the number wanted.

Stored Roots.—All Beetroots and Carrots ought now to be stored. This must not be interpreted to mean that they are to be thrown in a heap in a corner of an outhouse or a cellar, as is far too frequently the case, but that they shall be properly stacked in heaps, with sand, fine dry soil, or other suitable material between the layers of roots. When they are thus correctly dealt with, the roots do not shrivel and there is no loss of quality, flavour, or nutritive value; whereas, when they are simply thrown anyhow and anywhere, the loss may be safely put at not less than one-half. The actual place of storage is not nearly as important as the manner of doing it, and as far as the former point is concerned, each grower may well consult his own convenience; but in respect of the latter there is no latitude, because the correct way is the only way.

Potatoes.—Stored Potatoes will cause a considerable amount of worry this winter, and it is imperative that examination shall be frequent to guard against serious losses through disease making itself manifest in the stocks. Although all the tubers were, as far as it was possible for one to judge, perfectly clean and sound when stored, it is probable that disease spores were on the skins or in the soil adhering to the skins. When the tubers are massed, as is necessary in storing, a certain amount of heat is generated, and the sweating which accompanies this combines to create a condition that is distinctly favourable to the germination of those spores, and the disease runs riot through the stock unless the cultivator is so wise as to examine the tubers often with a view to the instant removal of any that show the slightest indications of being faulty. This ought to be a wet-weather task, and its vast importance must be set against its decided unpleasantness. Late Potatoes not yet stored should have attention, exercising care to see that they are quite dry.

Vacant Ground.—Let all vacant ground in the vegetable quarters have immediate attention where the land is on the strong side. Bastard-trenching should be the rule, since this gives depth without changing the positions of the first and second spits. The top ought to be left as rough and lumpy as possible with a view to getting it well stored with water and then hard frozen, because these two things improve its fertility and mechanical condition. It is easy, when soil has had plenty of water and frost, to secure that beautiful tilth or season on the surface which is so favourable to the sowing of seeds or the planting of plants. Light, sandy soil is almost invariably better left lying solid through the winter, to be worked as early after the turn of the year as the

state of the weather will permit. Manuring should be done at the time of working, in both instances.

Liming.—When garden ground has been exclusively manured with natural excrement for five or six years, this material should be entirely withheld and full reliance placed upon concentrated fertilisers for a season. In the autumn—now—lime should be spread on the rough surface until it is perfectly white—not a vestige of the brown earth must be observable—and after eight days it may be lightly pointed in with a fork; but this is not really necessary, as it will assuredly find its way down. This will sweeten the ground and vastly improve its fertility. H. J.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

TO PLANT VIOLETS IN A FRAME (Hex).—You may prepare a hot-bed of manure and Oak or Beech leaves, trodden firmly, so that a fierce heat will not be generated. Place the frame in position, and over the manure put 4 inches to 6 inches of loamy soil. Tread moderately firmly and plant the Violets so that the outer leaves almost touch. Water at once and keep the frame fairly close for a few days; then admit air in the daytime. You may also use a frame without any heating material; but the most satisfactory results are obtained when a little warmth is provided. We do not consider that Violet Mrs. J. J. Astor is very suitable for planting in Rose-beds, and suggest that various *Violas* be used instead.

HONEYSUCKLES AND SAXIFRAGES (R. S. D.).—Two good Honeysuckles are *Lonicera flexuosa* (flowers red and cream, very sweet-scented) and *L. sempervirens* (the scarlet trumpet Honeysuckle). Both are good and free in growth. The China Rose named is of moderate vigour only, and not quite suitable for the high fence named. American Pillar, Jersey Beauty, or Hiawatha would be more serviceable. The Saxifrages may be raised from seeds, though if you have no experience in such matters we do not advise you to undertake the work at the start. The Mossy varieties are easily raised, though the seedlings, naturally, contain many of a woody or poor character, while the seedlings of the eucrosted sorts often move very slowly. In all the circumstances you had better purchase a select lot of plants. As, however, you intend the rock garden for these alone, it should be arranged to meet the requirements of all or several sections, as a position suited to one of the *Bursicrana* set would be useless for the larger-growing Mosses or the big-leaved *Megasea* group. A single plant of the former would require but the merest chink or crevice with a free root-run to grow in.

TREES AND SHRUBS.

TO REMOVE DOUBLE-FLOWERED GORSE (T. H. K.).—Gorse, either single or double flowered, is not an easy subject to transplant. As your plants are not more than two years old, you may succeed with some of them, however, especially if you cut the branches well down at the time of transplanting. The work should either be done at once or left until late spring; midwinter would not be a good time for it. As a rule, the double-flowered Gorse is raised from cuttings inserted in a cold frame. When rooted, the young plants are potted singly into small pots. They are grown in pots until planted in

permanent positions. It would be a good plan to use some of the smaller shoots from your plants for cuttings to make up gaps where others die.

EVERGREEN FOR FRONT OF HOUSE (Wharfedate).—You will probably find that *Crataegus Pyracantha* or its variety *Lelandii* will suit your purpose better than anything else. Both grow fairly rapidly when once established, and have small, dark, evergreen leaves, bear white flowers in May and scarlet fruits in September. You had better obtain a plant established in a pot, for plants taken up from the open ground do not establish very well.

TO KILL THE STUMP OF A TREE (R. T.).—If you bore two or three holes, each 1 inch in diameter, into and to the centre of the trunk, and one hole into each of the main roots, and fill them with common salt, you will have no difficulty in killing your tree. Oil of vitriol would have the same effect, but it is dangerous to use. There is no necessity to cut the stump right to the ground unless you wish to do so. Left uncovered it will probably look objectionable, but you can easily clothe it by planting Ivy or a climbing Rose at the base and training the branches round the stump.

THE GREENHOUSE.

ASPIDISTRAS (N. H.).—The *Aspidistra* naturally forms a creeping rhizome from whence the leaves and flowers are produced, so that it always travels away from the centre. At the same time, there is a certain amount of individual variation, some plants having this character in a more pronounced fashion than others. Keeping the barren side to the light will not in any way influence the production of shoots there, though, of course, the leaves will naturally draw towards the light. The only thing that can be done to remedy the present state of affairs is to divide and repot the plant. It is now late in the year to do this, hence we should advise you to keep the plant as it is till next April. Then turn the plant out of the pot and take away as much as possible of the old soil. This will enable you to see the rhizomes and the direction they take. In all probability such a plant as yours will be the better if made up into two specimens. A good way to do this is to divide the plant into four, and if the back portions of the rhizomes are leafless, a portion may be cut away. Then take the two portions which are to form one specimen, and place them so that the growing points of each are towards the centre of the pot. In this way a well-balanced specimen will result, and it will then stand for some years before it needs to be again treated in this way.

FRUIT GARDEN.

AUTUMN PEARS CRACKING (Miss M. H.).—The cracking of the Pears is due to the fungus *Fusicladium pyrinum*, causing the disease called Pear scab. This fungus attacks the shoots and causes them to crack in a somewhat similar

PEARS ATTACKED BY THE FUNGUS *FUSICLADIUM PYRINUM*. THIS CAUSES THE LARGE CRACKS.

manner, and we recommend you to have all the dead and dying wood pruned out of the tree during the winter, and then spray the tree thoroughly with a solution of 1 lb. of caustic soda to 10 gallons of water to get rid of the lichen and so on. These measures will entail some trouble, but the reward will be edible Pears if you follow it up by spraying with half-strength Bordeaux mixture in the summer, once as soon as the petals drop, and again about the middle of June.

PLANTING FRUIT TREES (J. B.).—You may plant fruit trees any time between now and the end of March provided the weather is open. The best months are November and February. You will find pruning and root-pruning, also the treatment of *Lozanberries* and similar fruits, fully dealt with in "Fruit-Growing for Beginners," price 1s. 3d., post free, from this office.

PRUNING APPLE TREES AND RASPBERRY CLUMPS (Hex).—Both these subjects may be pruned at once or any time before the end of January. After the latter date, if the weather is mild, the sap begins to rise, and a certain amount of bleeding may result. Be careful to coat all wounds on your Apple trees with coal-tar as soon as made. This will act as a protection against fungus-spores which may be blown about from cankered trees. You do not need to shorten Raspberry canes very

much; they may be left 4½ feet to 5½ feet high, according to strength. Do not leave too many rods to each clump; five or six are usually quite enough. We presume that you have already cut the old canes out, for that is usually done as soon as the fruit is gathered.

ROSE GARDEN.

LIQUID MANURE FOR ROSES (J. D.).—It is well to vary the food for Roses, and we would suggest the following applications given two or three times a week in the growing season, varying the kinds as often as possible. It is well to have separate tubs and to allow the liquid to stand five or six days before using: Nitrate of soda, or sulphate of ammonia, half an ounce to 1 gallon of water; superphosphate of lime, 1½ oz. to 1 gallon of water; guano, 1 lb. to 18 gallons of water; cow-manure, 1 gallon to 1½ gallons of water; soot, 1 gallon to 18 gallons of water.

ROSES AND HEAVY SOIL (Oaks).—In order to make your stiff clay soil more workable, we should advise you to add plenty of burnt clay or, failing this, to incorporate ashes and gritty road scrapings. But the burnt earth is best, and any handy-man would show you how to start burning some of the clay, which should be done at once. In September you should commence to trench the land, and, in so doing, add basic slag to the lower spit of soil at the rate of 8 oz. to the square yard. If you get the land trenched and have the top left rough, you will find the frost and winds will make the surface more pliable, and when in this condition add some spent Hops liberally and let them be incorporated with the top soil. The variety is General MacArthur, one of our very best red bedding kinds.

MISCELLANEOUS.

INSECTS IN WATER LILY POND (G. W.).—With further reference to your Water Lily pond, it may do good to clean it out again in winter and leave it empty for a time, especially if there is any frost. Frost, however, may kill the larvae in winter.

DODDER ON GORSE (H. M. P.).—The only chance of eradicating Dodder is to burn all affected parts and use the ground for some other subject until it is free from Dodder seeds. Even if you were to succeed in killing the Dodder without injuring the Gorse by the use of some spraying compound, you would have another crop next year from seeds which have fallen about the base of the plants; therefore there is no option but burning those plants which are affected and thoroughly clearing the ground.

TO OBTAIN THE HEIGHT OF STANDING TREES (S. F.).—The best way to obtain the height of standing trees is to obtain one of the several instruments which are manufactured for the purpose, such as Weisse's Hypsometer, Brandis's Hypsometer and Clinometer, or Stanley's Apocometer. The latter is very handy, and may be easily carried in the pocket. It is supplied, with directions for use, for one guinea. Most of these instruments are worked on the principle of determining the height by means of triangles formed by the tree, a base-line to a given point, and a supposititious line from that point to the top of the tree. Full descriptions are to be found in Vol. III. of "Schliek's Manual of Forestry." There are other ways, simple but less scientific. For instance, the height of a tree may be obtained by measuring the length of its shadow, and then, by simple proportion, calculating the height of the tree by comparing it with the length of the shadow thrown by a stake of given length. Thus, if a stake 10 feet high throws a shadow 15 feet in length, a tree throwing a shadow of 150 feet would be 100 feet in height. Such calculations should only be taken on level ground. The Bushman's method of finding the height of a tree is as follows: A stake is taken, with the distance above ground equal in length to the height of a man from the ground to his eyes. The stake is placed upright in the ground, and the man lies upon his back with his feet against the stake, and when he is in such a position that the top of the stake is in line with his eyes and the top of the tree, the distance from his eyes to the base of the tree is equal to the height of the tree.

UTILISING MASON'S LEAVINGS (E. H. D.).—We think you could turn the leavings of the mason to good account, and know of no better way of utilising the mixture referred to than by erecting a small rock garden. As there appears to be an abundance of sandstone locally, and as you give us no idea of the size of your formal garden or its surroundings, both the size and the arrangement would have to be decided by yourself after you had decided whether you wished merely to use the material you possess, or simply make of this a sort of nucleus for some larger arrangement. As your garden is hemmed in by a wall, we advise you to keep any rockwork entirely free therefrom, as such things are not infrequently a delusion. A better way would be to arrange raised rockwork beds, say, at the four corners of the square; or, if the garden is not of large size—everything, of course, would depend upon your own desires and upon ways and means—you might arrange a series of rockery beds, with intersecting paths to the central square. These need not exceed more than 2 feet or 3 feet that of the ordinary level, and by inserting a drainage of clinkers, or brickbats, or anything you can get, there would not be much fear of undue wet. The intersecting paths should be of gravel or finely-broken sandstone chippings. The sandstone blocks—than sandstone there is no better material for rock building or for plants—could be employed in building the erections, and the old mortar and other material for mixing with the soil. If the whole of the available soil inclines to retentiveness, sand, old mortar and plaster might be mingled therewith to the extent of one half of the bulk. The arrangement should be on a liberal scale; that

is to say, the spaces for the plants should be large—3 feet to 6 feet across—seeing that only those of free growth would be suitable. Literal apartments such as these would accommodate a dozen plants of a kind, which would afford sheets of colour. In this way quite a host of Saxifragas, alpine and other Ploxes, Campanulas, Achilleas, Primulas, Polygonums, Litospersum, Sedum, Iberis, Androsaces, Dianthus, Thymus, Erigerons, Prunella, Veronica, Coronilla, Aubretia and others might become a permanent feature and afford infinite pleasure. It might also be possible at small expense to have a bed for moisture-loving plants, Lilies, Primulas, Trilliums and the like. There is a wealth of material available, and many ways of utilising it to advantage. The best way, however, could only be determined on the spot.

LICHENS ON TENNIS LAWN (A. H. Sussex).—The ground must be in a very stagnant state to nourish specimens of lichens such as you send. The usual remedy in such cases is draining the ground; but on the slope of the South Downs, with a chalky subsoil, this ought not to be necessary. Is it possible the position is shaded by trees, or on the north side of a high building? So much depends on local conditions in such cases that it would be better to call in a local expert—the green-keeper of a golf course or county cricket ground, for instance. A dressing of lime might kill it; or if not a large piece of ground, it might be worth while digging it all over, leveling and resowing with Grass seed early in September.

NAMES OF PLANTS.—Coningsby and J. J.—See next week's issue.—W. B. B.—*Wallenia amherstiana*.—A. C.—1, *Begonia* seedling not named; 2, *Eschynanthus speciosus*.—J. D. B., Cambridge.—1, Irene Watts; 2, Mrs. E. G. Hill; 3, Mme. E. Resal; 4, Queen Mab; 5, White Pet; 6, Aurora.

NAMES OF FRUIT.—W. H. Stabler—Grape Black Hamburgh.—W. T. Brunger.—The Pear arrived rotten and we were unable to identify it.—Healing.—1, Marie Louise d'Uccle; 2, Doyenné du Comice; 3, Mariéchal de la Cour.

SOCIETIES.

BRIGHTON AND SUSSEX CHRYSANTHEMUM SHOW.

THE thirtieth annual autumn exhibition was held in the Dome and Corp Exchange on November 5 and 6. Unfortunately weather marked the occasion, but its effect was scarcely perceptible in the matter of exhibits or in that of attendance. In regard to the former they possessed a very high degree of excellence, displaying the cultivators' skill in a marked degree, especially in the large classes for cut-blooms, where competition was very keen. The following constitute the primary awards:

For a circular group of Chrysanthemums arranged with Ferns or other green foliage plants for quality and effect in a circle 8 feet 6 inches in diameter, the first prize, a handsome silver cup and the society's silver medal, fell to S. C. Witting, Esq., Patcham (gardener, Mr. G. Chaudler).

For a circular group of Chrysanthemums only, Dr. Tulk-Hart, Brighton (gardener, Mr. J. Adis), scored.

For twelve bush plants, Pompons only, not fewer than eight varieties nor more than two of one variety, P. H. Bayer, Esq. (gardener, Mr. G. H. Bennett), was first, followed by S. Copstake, Esq., Hove (gardener, Mr. A. Sayers), and C. A. Wood, Esq., Brighton (gardener, Mr. S. Watkins). In addition to the first prize were a handsome silver cup and the society's silver medal.

CUT BLOOMS (OPEN).

For thirty-six Japanese, not fewer than twenty-four varieties nor more than two of one sort, a handsome silver bowl, the society's medal and first prize fell to G. L. Wiggs, Esq., Merstham (gardener, Mr. M. Sargent); second, Colonel C. P. Henty, Avington, Arundel (gardener, Mr. J. Harris); third, Mrs. L. C. Goad, Worthing (gardener, Mr. Charles Hack); fourth, the Rev. F. S. Selator, Lewes (gardener, Mr. J. E. Hickson); and an extra prize to L. Breitmeyer, Esq., Cuckfield (gardener, Mr. Hugh MacFadyen). There were six entries; the keenness of the competition will be recognised by the number of awards. The first-prize collection, which was remarkably fine and even, contained grand specimens of Frances Jolliffe, Mrs. Gilbert Drabble, Master James, William Turner, F. S. Vallis, John Peed, Willie Rawlings, Purity, Frank Payne, W. Mease, Mrs. L. Thorn and Mrs. R. Luxford.

For twenty-five Japanese as cut from the plants, not fewer than eighteen varieties, the premier award fell to H. Ramsbottom, Esq., Crowborough (gardener, Mr. A. Jewell), who showed magnificent blooms of Thorpe Beauty, Mme. G. Rivol, Mary Poulton, Mrs. Charles Beckett, George Milham '08, Mrs. C. H. Totty and Mrs. G. C. Kelly. Messrs. James Stredwick and Son, St. Leonards-on-Sea, were second, with L. Breitmeyer, Esq., third.

Twelve Japanese large-flowered, distinct: First, Mr. C. Fox (amateur), Tunbridge Wells, with fine blooms of Mrs. A. T. Miller, Alice Lemon, Lady Carmichael, Kara Dow, Lady Talbot and Master David; second, C. E. d'Avigdor Goldsmid, Esq. (gardener, Mr. Charles Earl).

Six incurved Japanese, large-flowered, distinct: First, Colonel Henty; second, Dr. House, Worthing (gardener, Mr. A. E. Clarke).

Six Japanese, one variety, any colour: First, L. S. Wigg, Esq., with Frances Jolliffe; second, Mr. W. H. Apted, Worthing, with W. Mease; third, Mrs. L. C. Goad, with Rose Pockett.

Six incurved, any one variety: First, Colonel Henty, with Clara Wells; second, Mr. Frank Green, with Romance.

Twelve Japanese Chrysanthemums (amateurs' division), not fewer than nine varieties nor more than two blooms

of one sort: First, Mr. C. Fox; second, Mr. T. West third Mr. J. J. Burrows. Accompanying the first prize was a silver challenge trophy, which now becomes the absolute property of Mr. Fox, who has succeeded in winning it three times and that in three successive years.

ROYAL HORTICULTURAL SOCIETY'S ORCHID CONFERENCE.

IN connection with the brilliant and remarkable exhibition of Orchids at the Royal Horticultural Hall on November 5 and 6, a conference was held in the Lecture-Room on Wednesday. A good audience of those interested in the breeding of these plants was present at each of the sessions, and excellent papers were read, albeit not couched altogether in the language of the unlearned. Mr. J. Gurney Fowler, the chairman of the Orchid committee, presided at both meetings, and kept the conference within the bounds of time set and the limits of discussion in the admirable manner one has learned to expect of him.

Professor F. Keeble, M.A., of the University College, Reading, read the first paper on "The Physiology of Fertilisation." He gave a brief outline of the history of our knowledge of the phenomena of fertilisation, a knowledge which is of comparatively recent growth and is still far from perfect. He pointed out that it was essentially the fusion of two masses of living stuff into one whole, one from the pollen tube, the other from the ovule. The whole of the curious phenomena of growth and development of the flower was aimed at securing the proper carrying of the pollen nucleus to its destination. Recent research had shown that this fusion was not always absolutely necessary to secure the development of an egg into an embryo. In some curious cases, such as that of *Zygopetalum Mackayi*, no matter with what pollen the stigma was pollinated, whether it be an *Odoontoglossum* or member of another genus, the seeds produced gave *Zygopetalum* pure and simple. Did fertilisation really occur here? One could not suppose it did. Pollination apparently brought about stimulation of the ovules to develop as well as a mass of living stuff to the egg-cell, and it was probably this stimulative effect that resulted in the production of seeds in *Zygopetalum*, quite apart from actual fertilisation. Experiment had shown that both chemical and mechanical stimulation would bring about similar results in certain cases. A brisk discussion followed, and many interesting points were raised and observations made.

Major C. C. Hurst's paper on "The Application of Genetics to Orchid-Breeding" was followed with equal interest. He referred to the extensive part the Royal Horticultural Society had taken in propagating a knowledge of genetics, and to the enormous progress the study had made during the past few years. He thought that if only the principles of genetics (which he detailed) were followed to a conclusion, much time might be saved, and certainty of result instead of chance would be gained in raising the desired scarlet *Odoontoglossum* or scarlet *Cattleya* or yellow *Cattleya*, and similar things still only dreamt of. The Orchids might have a stud book, and those known to yield good offspring because they were "pure bred" would acquire a stud value just as pedigree stock did, and with it an enhanced commercial value. He went further and showed how these pure-bred races might be obtained. Mr. Crawshaw perhaps touched on one of the greatest difficulties met with in testing the pureness or otherwise of a stock in the enormous mortality of the seedlings. But if this purity can be tested, there is no doubt that chance, with its prodigious number of useless plants, would give place to certainty in raising not only these but other plants.

After the interval for lunch, Mr. H. G. Alexander read his paper on "Epiphytic Orchids," and dealt with the principles of their cultivation in a most masterly manner. Everyone who has seen Sir George Holford's splendid exhibits will know that his Orchid-grower is no mere theorist, and when he insists on the importance of ample light and efficient ventilation at all times in growing such plants as *Vandas*, *Cattleyas*, *Lachias*, *Dendrobiums* and so on, attributing much more importance to light and air than to heat, one knows he is preaching his own admirable practice. One question often asked is, "Should epiphytic Orchids be manured?" Mr. Alexander gives an emphatic negative. Another, "How often should Orchids be watered?" Mr. Alexander says (and every grower will agree with him) no man can answer that question. He insisted on the need for a study of the conditions under which the plants were grown, as well as the state of growth of the plant. A host of cross-questions followed Mr. Alexander's paper, and to them straight answers were promptly returned, to the benefit of all present.

Then followed Mr. Thwaites' paper on the raising of albino Orchids and his remarks on the difficulties he had experienced in raising them and in understanding the various theories regarding them that had been propounded from time to time. However far one may be inclined to follow his conclusions, everyone will certainly agree with his remarks as to the desirability of not naming merely whitish forms "alba," but confining that term to real albinos. Mr. Thwaites' remarks called up considerable discussion, and one must wait to study the full text of his paper and that of Major Hurst, who dealt with the same subject, before one can see precisely the value of their respective arguments.

Sir George Holford, in moving the vote of thanks to the chairman at the end of the meeting, confirmed the remarks of his Orchid-grower concerning the need of light and airy situations and structures for the growing of Orchids, and deprecated the use of close and dark houses and permanent shading upon them. Needless to say, growers will take his words to heart, and we shall see fewer cases of mortality among Orchids brought about by partial starvation through lack of light, and suffocation through lack of air.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Fruit Research Plantation for South-Eastern Counties.—At a meeting of the Governors of the South-Eastern Agricultural College, Wye, on Monday, the 11th inst., the proposal to establish a fruit research plantation in the South-Eastern District was considered. It was decided to accept the responsibility of administering such a plantation with the aid of the grant of £500 offered by the Board of Agriculture. We hope that the researches and experiments will be of a practical as well as a scientific character.

Erigeron Quakeress.—Hardy, elegant, free-flowering and profuse, this is destined, we think, to figure with the indispensable plants of the good herbaceous border in the near future. Indeed, it would do so the moment it is known, since its good attributes are as clear as the day. The colour, which in the summer-time is deepest mauve, assumes a paler tone in its latter-day developments, while there is a refinement withal—habit and flowering alike—that is not given to any of the forms of *E. speciosus*.

The Rock Garden at Kew.—Further alterations are now proceeding in the rock garden at Kew. In the position formerly occupied by the dripping well will be a ravine, through which will flow a cascade. The latter, after passing through a series of four little waterfalls, will empty into a bog garden. When completed, the alterations will form a great improvement, and will be quite in keeping with the general construction of the rock garden, which resembles the rocky course of a stream such as may be met with in the side valleys of the Pyrenees.

Rose Gloire de Dijon as a Standard.—One is fairly accustomed to seeing this Rose trained to walls and fences, but not so often as a standard. At the beginning of November we had quite a number of expanded flowers, and several more buds fast developing on a standard specimen. Of no other variety in standard form could this be said. Should anyone be trying this variety for the first time in this way, we would add, do not prune too hard, and if a shoot or two is long enough to arch over and tie to a stake, so much the better. Practically every bud will break and flower.

Variation in Ferns.—The variation in *Nephrolepis exaltata* is wonderful, and is all the more remarkable from the fact that though, according to the "Dictionary of Gardening," the original species was introduced as long ago as 1793, it is only within the last decade or so that this extreme variability has manifested itself. This was not due to it being but little grown, for *N. exaltata* has long been a popular market Fern, especially in the United States, where it is commonly known as the Boston Fern. The first plumose forms, too, came to us from across the Atlantic; but now

we have in this respect outdone the Americans themselves, the most extreme form in mossy development being represented by the variety *Willmottæ*, which was given an award of merit by the Royal Horticultural Society on November 5.

Oil from Sunflower Seed.—The annual report on the work of the Imperial Institute during 1911, just published, contains the following note on Sunflower seed: "A sample of this seed was received from the Sudan. The kernels yielded 47.9 per cent. of oil, equivalent to about 22 per cent. expressed on the whole seed. The oil was bright yellow and somewhat viscous, and would be suitable for edible purposes after refining. The residual cake would be suitable for use as a feeding stuff. So far Sunflower seed has not been largely worked in the United Kingdom as an oil seed, but experiments in its utilisation have been made recently in Hull."

Winter-flowering Sweet Peas.—In Bulletin No. 319, just issued by the Cornell University, Ithaca, New York, Mr. A. C. Beal describes in detail experiments which have been conducted with winter-flowering Sweet Peas at the Cornell University. We have on some previous occasions dealt fully with the *Télemly* varieties, and also those that originated with Mr. Engelmann of Saffron Walden. The trials at Cornell University were conducted mainly with a view to ascertaining the time it took from seed-sowing to get plants to the flowering stage. The Engelmann varieties took from 101 to 110 days; Paul's Improved *Télemly* varieties, 92 to 160 days; and Arkwright's *Télemly* varieties, 88 to 107 days. Descriptions of all the varieties sent for trial are included in the bulletin.

The Pollination of Fruit Blossom.—In the current issue of the Journal of the Royal Horticultural Society, Mr. Cecil H. Hooper's lecture on the above subject is printed in full and makes most interesting reading. We quote the following from the summary: "It seems as if in the open field or garden Strawberries are pollinated by the movement of the air. Raspberries and Loganberries need insect pollination. The Raspberry is more dependent on insect pollination than the Loganberry. Hive bees are very fond of Raspberry blossoms, and even more so of those of Loganberry. In Gooseberries and Currants it is of the utmost importance to have plenty of hive or bumble bees near, as no fruit is set without them. They are also a necessity in the case of Pear, Apple, Cherry and Plum. With our present knowledge it seems advisable in planting to alternate the variety in each one or two rows, choosing varieties that blossom at about the same period. In gardens do not plant single trees of a kind, all trees of one variety together, but rather intermix the varieties. Keep hive bees, especially in suburban gardens and on large fruit farms, and in districts where large areas of the same kinds of fruit are grown."

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Bardou Job Flowering in Mid-November.

That excellent Rose Bardou Job is flowering still on the base of an outside conservatory wall, where it is trained to climb horizontally. I have to-day (November 16) gathered sufficient of these Roses to fill a vase, and several buds—if the frost will allow—will give yet another vaseful in a few days. This Rose commenced flowering on my conservatory in May. The very decided otto of Rose perfume is as strong now as it was in the hot weather.—ELEANOR G. SHELLEY, *Alresford, Hants.*

Nicotiana affinis in November.

Of late years I have been shy of using this good plant in flower borders because of its way of drooping with half-closed flowers in daylight; but two days ago, in the middle of a time of bitterest winter weather, it showed itself to be a valuable hardy flower for cutting. A belated patch, sheltered by a group of Hydrangeas, bore several shoots of perfect bloom—the flowers wide open, evidently taking the dim wintry light for twilight. A good bunch of Iris *stylosa* had just been brought in, and I was seeking for something to accompany them. The white Tobacco seemed to be the immediate answer to the search, and, with some small branches of bright green foliage of *Skimmia oblata*, has made as charming a winter bouquet as one could wish to see.—G. J.

Large-flowered Climbing Roses.—In a recent note a contributor regretted there were so few Roses of this class, but he overlooked those two grand deep crimson, scented flowers Ards Pillar and Ards Rover, Hybrid Teas, eminent also for hold, handsome foliage and perpetual flowering, while they often make a growth of 9 feet in a season. Lady Waterlow was very rightly named. I might also mention Johanna Sebus, reddish blush, of the Dijon breed, exquisitely scented. The term "climbing" properly refers to rambling Roses, but there is a class of half-rampant Roses suitable for pillars that are very welcome, such as Climbing W. J. Grant, Climbing Lady Ashtown and Climbing La France, all well worth attention. A very fine single, rapid climber, with large blooms produced in clusters of rich pink, is American Pillar. Billiard et Barre is a showy pillar Rose of deep gold, Gustave Regis is pure yellow, and Climbing Frau Karl Druschki white; while such Hybrid Perpetuals as Hugh Dickson, J. B. Clark and Bardou Job (Hybrid Tea), of fiery crimson, are good pillar Roses, also Mme. Jules Gravereaux in the creamy blush colour. I think also that the rugosa hybrids Juliet (fiery orange) and Conrad Ferdinand Meyer (silvery blush) will make useful pillars.—GEORGE BUNYARD, *Maidstone.*

Bitter-pit in Apples.—Last year I drew attention to the remarkable prevalence of the Apple trouble known as bitter-pit, and in THE GARDEN for March 30 last gave a table comparing the weather with the prevalence of the disease in different years. The disease has been known for at least fifty years, and up to the present its occurrence seems to depend upon the weather conditions and the water supply more than upon anything else. This season the trouble is, fortunately, rarely met with. I have seen it in very few varieties in any part of England, either at exhibitions, in the market, or in the garden itself. Warner's King has suffered in some places, and possibly some few other soft-fleshed fruits, but to nothing

like the extent to which they suffered last year. I have not met with it in any hard-fleshed Apples this season. These facts make a comparison of this season's temperature and rainfall with that of last most interesting, and, as will be seen, the comparison supports my original suggestion as to the connection between the weather and the disease. I give last year's weather record for August and September and that of the corresponding months of this year side by side, so that comparison may be the more easily made.

—SCIENTIST.

A Useful Winter Endive.—Sutton's Winter Lettuce-leaved Endive is being much enjoyed here just now, used as a simple salad with cheese. We blanch it by tying the plants up tightly with raffia when they have attained full growth, and placing a large inverted flower-pot over each, with a crock over the drainage hole and a handful of soil thrown on top of that. This little extra trouble ensures a much finer and better blanched plant than the ordinary slipshod method of laying slates on the top. I even go to the trouble of covering a number every week (on a dry day) and numbering the pots, so that we may know which to use first. After three weeks or a month we find large, crisp heads of a beautiful ivory whiteness and with a flavour reminiscent of Cob Nuts, far superior, in my opinion, to that of any of the curled Endives that are so much grown, and which are, after all, more in the nature of a simple garnish to a salad than an appetising adjunct, such as the finely-flavoured plant of which I am writing. I would mention that we get our best Endive here from plants that have been put out on beds cleared of Daffodils. They evidently like the bone-manure that remains in the soil.—F. HERBERT CHAPMAN, *Rye.*

Saxifraga burseriana "tridentata."—I for one am grateful to Mr. Farrer, page 574, for his timely lifting of the veil from the above absurd name, and for furnishing, in his usually lucid authoritative style, not only the correct name, but the "why and the wherefore" of it at the same time. To me the name was ever a puzzle, and I well remember, when first seeing it, asking the reason why and pointing to its meaninglessness and absurdity. The only excuse for the error is the not very distant step between "tridentina" and "tridentata," and the corruption, doubtless, has been due to had writing, a blurred or indistinct labelling, or similar cause. I am interested, too, to know more of the history of this fine form, which, curiously enough, I characterised on seeing it as not far removed from the true S. b. major of the Dolomites. It is, indeed, so far as my plant of it at present indicates, a somewhat more tufted form, major spreading laterally more than the others. Now one knows that major, Gloria, magna and tridentina are, as it were, an exclusive set apart—a glorious quartet—each an aristocrat in its way, and as such fitted for association with the choicest and best. They are all desirable, too, not for their inimitable beauty alone, but also because, flowering at divers times, they ennoble their race thereby while enriching our rock gardens and alpine-houses for a more extended season

with precious gems of which a few years ago we had not even dared to dream.—E. H. JENKINS.

The Deciduous Cypress Fruiting.—The note by "W. D." and the illustration showing a cone-bearing branch of the above-named tree, page 562, November 9 issue, are very interesting. In the gardens at Cadland Park, near Southampton, there is one of the finest specimens of the Deciduous Cypress in the United Kingdom. For more than ten years I had charge of the gardens, and while there noticed fruits on the branches several times. I had the tree measured. Ten years ago it was more than one hundred feet high and measured 14 feet round the trunk at 4 feet from the ground. The position was at the head of an ornamental pond; the "knees" grew up from the sloping grass bank, and many roots permeated the mud at the bottom of the pond. The trunk had a clear rise, free from branches, for about twelve feet. Two other specimens, about thirty-five feet high, grew in boggy ground near. More trees should be grown in the country than there are at present, but in suitable positions.—G. G.

The Grading and Packing of Fruit.—In reading your report of the Kent Commercial Fruit Show on page 568 of November 9 issue, I see mention made of the Federation boxes. It would be interesting to know the measurements of these and where they can be obtained. I am also interested to know what a London bushel of Apples is, and especially how it is arrived at. Are the Apples measured? I am told that most growers send 40lb. to 42lb. of Apples for a bushel, and therefore I judge it must be a measure, for surely a grower cannot fix the weight of his Apples at a variable total if they are sold by weight. In the Midlands Apples are sold by the peck, and 16lb. is the weight of a peck, so 64lb. make a bushel. It seems to me that we must be selling on very bad lines if 42lb. suffice for a London bushel. Pears and Plums are worse still, for 18lb. are supposed to be a peck. Seeing that an Act of Parliament was passed many years ago making the selling of fruit by measure illegal, would it not be better if all fruit were sold by the imperial stone or hundredweight? If this were done, market reports would be understandable and of value to readers all over the country, whereas at present they are misleading or, as is often the case, convey no information whatever to the reader. Passing on to another subject, your correspondent "B.," page 562, says, "Marie Louise is generally grown on a warm wall." My experience is that on a warm wall it blooms so easily as to be generally destroyed by spring frosts, whereas on a wall facing north-west or east it succeeds admirably. Again, in the case of Plums, I suppose the number of trees of Victoria planted on walls equals nearly all the other varieties put together, and yet the fruit is spoilt on a warm wall, and it is perhaps the worst of all Plums for training owing to its habit of growth. The best way to grow Victoria is as a standard or half-standard and keep the pruning-knife away from it, and reserve the walls for those varieties which are improved by being planted on them.—A. H. PEARSON. [The size of the boxes for fruit was given in an article on fruit-packing on page 440 of our issue for August 31. It is 20 inches long, 14 inches wide and 10 inches deep. At the time of going to press we have not been able to ascertain where they can be obtained. The so-called bushel sieve sent to the London market holds, approximately, 3½ pecks. We agree with Mr. Pearson that selling by weight is by far the best.—Eo.]

Daffodils in an Orchard.—From time to time we have called attention to the picturesque effects that may be obtained by growing Daffodils in grassland. At no time do these flowers appear to greater advantage than when grown under the partial shade of old Apple or other fruit trees. The accompanying illustration depicts a charming spring scene in Mr. G. Hawker's orchard at Strode, Ermington, Ivybridge.

Edwardsia or Sophora grandiflora.—As so much has been said in favour of the Kowhai in your columns of late, it may be worth while stating that it is hardy and flowers well in some parts of the South-West of Scotland, especially near the sea. It cannot be considered a good tree for inland gardens in Scotland, as, so far as I know, there have been no successes with it in the open in gardens away from the sea. I know of a few places where it has been established for a good many years, and where it flowers well annually. It is very beautiful with its handsome clusters of golden yellow flowers.—S. ARNOTT.

Pentstemon Newbury Gem.—Any grower desirous of securing a fine subject for massing could not do better than choose the above-named plant. It is a dwarf, compact Pentstemon, producing innumerable scapes covered with small crimson-scarlet flowers. There are also a White Newbury Gem and a Pink Newbury Gem, the latter being a beautiful soft shade of rosy pink, and is not only valuable for bedding purposes, but is suitable for cutting and house decoration. The plants bloom throughout the summer and autumn months if the leading shoot is pinched out when the flowers are passed, thereby inducing many side growths to form, which soon give a good account of themselves. In addition to those already quoted are Myddelton Gem, a pleasing shade of pink, and Southgate Gem, which is scarlet in colour.—T.

Geranium wallichianum.—From time to time notes have appeared in commendation of this plant, and yet it is but comparatively rare that one finds it in collections of hardy plants. This, to me at any rate, is somewhat surprising, and can only be, I think, because its merits are not known, as I know of few plants which better deserve a place in the hardy flower garden. Its season of flowering is a long one. A plant in these gardens has been flowering profusely for over two months, and has every appearance, weather permitting, of continuing to flower for some time to come. It is certainly one of the most charming plants we have at this season. It is quite a good border plant, but I prefer it on a sloping bank or on the rockery, if one has room for it, as it soon covers a large space, and would be out of place, besides being a danger to other plants, on any but a large rockery. The flowers are a delicate shade of blue, with a central zone of white, with dark lines radiating from the centre to nearly the outer edge of the petals. The plant grows from 3 feet to 6 feet high.—J. D. HALIBURTON, *Botanic Gardens, Bath.*

FORTHCOMING EVENTS.

November 28.—Hull Chrysanthemum Show.

December 2.—National Chrysanthemum Society's Floral Committee Meeting at Essex Hall at 3 p.m.

December 3.—Royal Horticultural Society's Meeting and Perpetual Flowering Carnation Society's Show (two days) at Vincent Square, Westminster.

SOME WINTER EFFECTS OF FLOWER AND SHRUB.

NO garden, if thoughtfully planted, need be without an appreciable amount of bloom on hardy plant and bush during the winter months. No reasonable person expects to find flowers flourishing in actual frost; but in all the milder spells that occur throughout the cold season there are a number of flowers that may be trusted to appear faithfully. Towards the end of November there is the large Christmas Rose, coming into bloom a good month before the others of its kind. The flowers are of large size and great substance. By the middle of December there will be the yellow Winter Jasmine, that will go on for some weeks; and from November onwards, in all open weather, flowers may be gathered from the charming Winter Iris (*I. stylosa*). It is true that in the last few winters, since there have been rainy and comparatively sunless summers,

the sweetest of the garden's flowers. The Winter Sweet (*Chimonanthus fragrans*), with its excellent and penetrating perfume, is another shrub-bloom of midwinter, though it is hardly showy enough to class among flowers of special effect. The Witch Hazel (*Hamamelis*) bears some resemblance to the Winter Sweet, in that the blossoms come closely set on the leafless shrub and have the same kind of yellow colouring. But though the petals are much narrower, and are curiously twisted, the bloom is so abundant that it has a distinct effect as a flowering shrub; moreover, it is hardier and can be planted in the open.

But though we have all these precious winter flowers, the greater value of the garden will be in the deep, rich colouring of our best evergreens—Yew, Box, Holly, Cypress, Bay and Ilex, to name only some of the more important. Then, of lowlier shrubs, *Berberis Aquifolium*, in its many colourings of green, red and varying shades of ruddy bronze is of the utmost value. There are also *Skimmia*, *Andromeda* and its allies, and the beautiful *Alexandrian Laurel* (*Ruscus racemosus*). *Rhododen-*

AN EFFECTIVE GROUPING OF DAFFODILS IN AN ORCHARD AT STRODE, ERMINGTON, IVYBRIDGE.

this capital plant has been more shy of bloom. It is a native of Algeria, and it would seem probable that a vigorous bloom may depend a good deal on such a thorough ripening of the rhizome as it always receives in its natural habitat. It is therefore desirable to give it a dry and sunny place, such as on a slightly-raised border against a south wall, in rather poor soil; for we find that in richer ground it produces very large leaf growth and but little bloom. There is also a beautiful white variety. Also from November onwards *Czar Violets* should be in flower. After Christmas, *Snowdrops* and the little yellow *Winter Aconite* make charming effects in wild ground, such as beneath trees in thin woodland; the *Winter Aconite* will even grow under *Beeches*.

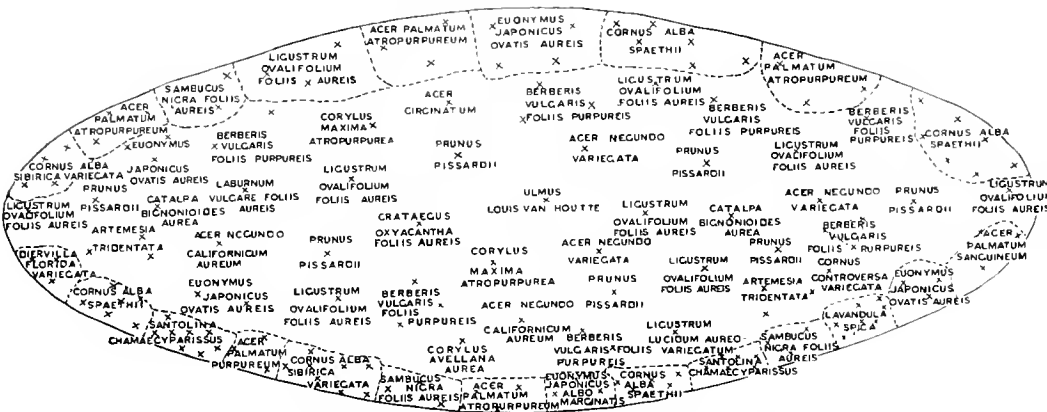

Periwinkles are flowers of February, prettiest also on banks in wild ground. The same month brings the blossom of *Daphne Mezereum*, whose low-toned pinkish bloom, coming before the leaves, reminds one, by its strong, pleasant scent, of the several others of its family that are among

drons, especially those of the *ponticum* class, are in their deepest and glossiest foliage. Besides these, we have the evergreens of grey and glaucous colouring—*Junipers*, *Deodar* and *Picea pungens*, *Retinospora* and others. Some of these also take on a ruddy tint in winter. But there are trees and shrubs of quite other colouring; a whole range of gold-variegated varieties that can be used with excellent effect, especially if grouped rather near together. Of the trees, the *Golden Hollies* and *Cypresses* are among the brightest, and among shrubs the *Golden Privet* is of fine colouring and has the good habit (although it is really deciduous) of holding its leaves till well after Christmas. The gold-variegated *Elæagnus* is also one of the handsomest of shrubs with coloured leaves. The gold-splashed *Euonymus* is only hardy in the South; even at an hour's journey south of London it is generally spoilt by frost. The hardy *Bamboo*, *Arundinaria japonica* (more commonly known in gardens as *Bambusa Métake*), is bright and cheerful through the worst of the winter.

Delightful effects of red and yellow colouring may be obtained by rather large plantings of the yellow and scarlet barked Willows and the Red Dogwood. For this kind of use the Willows should be cut down every year at the end of the winter, for the shoots of a year old are the brightest in

spring till autumn, providing the grouping of the colours is carefully done. The accompanying plan of such a border at Kew, 120 feet long and 40 feet wide, will give readers an idea of the grouping. At first sight the plan appears to be crowded, but it is quite easy to go over such a

foliage to form coloured clumps which are beautiful throughout the year, it will be found by experience that the foliage of deciduous trees and shrubs is, generally speaking, more brilliant in colouring than those with persistent leaves. Those mentioned below have brightly-coloured foliage, and are very suitable for the purposes referred to in these notes.

PLAN OF A BORDER OF ORNAMENTAL-FOLIATED TREES AND SHRUBS. THE PROPER ARRANGEMENT OF THESE AT PLANTING-TIME IS VERY IMPORTANT.

colour. It should be remembered that two of our hardy Ferns, namely, Polypody and Hart's-tongue, are at their best in early winter. At the same season, in some years, masses of berries on Hawthorns, especially when wet with rain, are surprisingly bright in colour. When there are very few Holly berries, we much miss their brilliant scarlet in the case of trees that usually bear well. Where Mistletoe grows freely, as in some places where there are old Eime trees, the bright yellow-green of the great bush-like masses has a strange effect by contrast with the grey stems and branches of the leafless trees; for it looks as if all the life were in the parasite only. Many people have been disappointed by trying to grow this handsome thing from the berries taken from branches cut for winter ornament; the berries are then quite unripe. They are not fit to sow till April. G. JELLYL.

border in March each year and shorten the long growths of those which are trespassing into the space which should be occupied by their neighbours. In this way comparatively large shrubs, and in some instances trees, are kept trimmed to a moderate size. By cutting back the young shoots of the Golden-leaved Elder, Sambucus nigra foliis aureis, to within one or two eyes of the old wood each spring, vigorous young shoots push up, with plenty of leaves which colour better than those on old wood. The subjects planted at the back of the bed illustrated are somewhat shaded by trees in the vicinity, and are planted with the idea of furnishing in addition to colour effect. In front of the bed there is a wide stretch of lawn. The bed faces south, while behind it on the north side are a number of large trees, the green leaves of which form a useful and effective background.

Variegated Elm, Ulmus antaretica aurea; Van Houtte's Golden Elm, Ulmus Louis Van Houtte.

Deciduous Shrubs.—Japanese Maples, Acer japonica aurea and A. palmatum varieties; Purple Barberry, Berberis vulgaris foliis purpureis; Variegated Dogwood, Cornus alba sibirica variegata; Spæth's Golden Dogwood, Cornus alba Spæthii; Variegated Dogwood, Cornus controversa variegata; Golden-leaved Nut, Corylus avellana aurea; Purple-leaved Nut, Corylus maxima atropurpurea; Golden Privet, Ligustrum ovalifolium foliis aureis; Variegated Privet, Ligustrum lucidum aurea variegatum; Golden Elder, Sambucus nigra foliis aureis; and Variegated Snowberry, Symphoricarpos orbiculatus variegatus.

Evergreen Shrubs.—Gold and Silver Hollies, Ilex Aquifolium varieties; Variegated Box, Buxus sempervirens varieties; Golden Euonymus, Euonymus japonicus varieties; Variegated Elaeagnus, Elaeagnus pungens varieties; Lavender

TREES AND SHRUBS.

HOW TO ARRANGE ORNAMENTAL TREES AND SHRUBS.

NUMEROUS trees and shrubs of a deciduous and evergreen character are conspicuous by reason of their coloured foliage. Unlike flowers, fruits or the autumn tints, which are all more or less of short duration, trees and shrubs with coloured foliage last in good condition for a long time, the deciduous ones throughout the summer and the evergreens the whole year round. In small gardens it may be only possible to plant a few single specimens or mix in a few coloured-leaved shrubs with the green-leaved kinds in the shrubby border. Used in this way they are pretty, but the effect obtained is nothing approaching their liberal employment in the pleasure grounds and parks of large estates. Here large groups or masses of one kind may be planted to form a feature in the landscape, perhaps on sloping ground or by the lakeside.

A border or large bed of mixed coloured-foliaged trees and shrubs gives a charming picture from

FLOWERING SHOOT OF STYRAX JAPONICUM, A BEAUTIFUL BUT LITTLE-KNOWN HARDY SHRUB.

ROSE SUNBURST.

Cotton, Santolina Chamæcyparissus; Lavender, Lavandula spica; United States Sage Bush, Artemisia tridentata; Tree Purslane, Atriplex Halimius; several Tree Ivies, Hedera Helix varieties; and numerous conifers, especially varieties of Cupressus.

A LITTLE-KNOWN FLOWERING SHRUB.

(STYRAX JAPONICUM.)

Thus is a large deciduous shrub or small tree, native of Japan. A fairly sheltered position is the most suitable, as, although the flowers do not open till June, on several occasions we have had the buds on trees in open situations ruined by late spring frosts, while a tree in a sheltered position has entirely escaped. The soil should be fairly light and well drained, a mulching of leaf-mould and manure being beneficial in summer. Nature has disposed the branches in a somewhat flat, spreading manner, the better to show off the white flowers. These are drooping, bell-shaped, about half an inch across and very freely borne on the branchlets, appearing several together from the axils of the leaves. As *Styrax japonicum* ripens seeds freely in this country, it should soon be fairly common, for if not hardy in cold districts, it is worth a place on a wall. The fruits are egg-shaped and the size of a hazel-nut. A. O.

previously received a card of commendation at the autumn show in 1909.

Mrs. Amy Hammond (S. McGredy and Son, 1911).—Another gold medal Rose of the National Rose Society, also awarded at the Salisbury Show in 1910, and those who have grown this Rose have nothing but praise for it. The raiser calls it "everybody's Rose"; it certainly has been very pleasing with me. I had some splendid flowers of it early in the season, good enough for any box, and I venture to think when better known it will be very popular. It found its way into a good many boxes this season, although it was only sent out last year. Its colour is not exactly describable in a few words. Flesh with a peach flush is as near as I can get it. The rosarian's "peach" is something quite distinct from the colour of the fruit. The flower is of excellent shape and size, sweetly perfumed, and the plant of vigorous, good branching habit. A Rose to be obtained at the earliest opportunity.

Stewart Clark, Frau Karl Druschki and others—a great victory this. It was equally good at the "National," and was very well shown at Belfast. I have found it remarkably easy to grow, and notwithstanding its shape and enormous number of petals, it opens well and freely. The petals have fine substance, and there is nothing tissue papery about them. Its foliage is remarkably strong and leathery, and has seven leaves instead of the usual five. Altogether a very distinct and beautiful Rose. *Southampton.* HERBERT E. MOLYNEUX

ROSE SUNBURST.

This variety is one of the latest of a whole series of beautiful yellow Roses which have come into com-

THE ROSE GARDEN.

NOTES ON NEWER ROSES.

HYBRID TEAS FOR EXHIBITION.

(Continued from page 580.)

Mrs. A. E. Coxhead (S. McGredy and Son, 1910).—It was rather surprising to me to see this Rose in practically every winning box in the early shows this year, and it also turned up smiling at the autumn show. It is, no doubt, accounted for by the fact that its shape is so nearly always perfect; and if the same could be said of its colour (as it can be said of its scent and habit of growth) it would indeed be one of the "great" Roses. But its colour is undoubtedly its weak point, and it is difficult to catch it right. It does not like tying, and shading does not appear to remedy the defect; but when this is said, one has said the worst. I hardly know a Rose that so frequently comes a perfect shape, and this, after all, is the main thing with the exhibitor. A big flower of fine colour with a bad split does not, and should not, count as much as a good flower perfect, except that it is a bit off colour. I do not mean a bad colour for the variety, but one that is naturally not a good colour. Mrs. A. E. Coxhead is one of these, Mrs. Stewart Clark another. No doubt Mr. Pemberton's eulogy of this flower when he described it as the best new Rose of the year has had a great deal to do with its popularity. I should not be doing this Rose justice if I omitted a reference to its perfume. It is delicious, and is as strongly marked in November as it was in June. It is a real good autumnal, and is seen at its best under artificial light, electric light for preference. It was awarded the gold medal of the National Rose Society at the Salisbury Show in 1910, having

ROSE DOROTHY PERKINS OVER A VERANDAH AT SHANKLIN, ISLE OF WIGHT. NOW IS THE TIME TO PLANT.

Mrs. Cornwallis West (Alex. Dickson, 1911).—Here is a Rose after the exhibitor's heart; a very delicate blush ivory white in colour, just sufficient colour in it to remove it from a pure white, but that is all. I see it described in some catalogues as "beautiful pink," but that is not correct. It is equally distinct in shape, getting away from the pointed petal. We have here a round Rose of the type of Her Majesty, only better. Globular, perhaps, is the correct term. Its growth, however, has nothing in common with Her Majesty; but, though vigorous, is as branching as any Hybrid Tea, with foliage that contrasts well with the flowers, which are produced singly on every shoot. It was the gold medal Rose of the Salisbury Show, and there were the unusual number of four. It has been splendidly exhibited by the raisers throughout the season. Commencing at Southampton, a box of twelve in a strong class of twenty-one entries for any white or pink won first prize, beating Bessie Browns, Mildred Grants, Dean Holes, William Sheans, a very fine box of Mrs.

merce recently. Until a few years ago good yellow Hybrid Teas were not in existence, but during the last decade hybridists have produced them in abundance. In Sunburst we have an excellent Rose, as it has perfume, lovely form, long lasting qualities, and above all, from a commercial point of view, excellent habit. A curious point about this Rose is that the second crop of blooms, as well as those produced from lateral shoots, come of a rich cadmium yellow, passing to yellow orange in the centre and without the white shading. It is very free-flowering and perpetual, and has already created quite a sensation in the commercial growing centres of America. Under glass it is a wonderful success as an autumn Rose, and I was recently informed by a commercial florist, who has some thousands in pots and planted out, that the demands, both of the home market and Paris, far exceeded the supply. Out of doors I should term it a glorified Mrs. Aaron Ward. The flowers for the coloured plate were supplied by Messrs. Stuart Low and Co. of Bush Hill Park. DANECROFT.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Continued from page 577.)

Rock-building.—Having considered the various types of rock, suitable and unsuitable, the operator has now to make his choice and to proceed to the more serious constructive work. It is in this connection that the chief blunders are made. Writers on the subject of rock gardening repeatedly urge the teachings of Nature without giving the least idea of the good and the bad so far as our own gardens are concerned. In Nature, of course, everything is right, though it does not follow that all her object-lessons would be alike suitable for our purpose. For example, we see in Nature great unquarried masses of rock that would be wholly unsuited to vegetable-life—have, indeed, been exposed for generations without attracting vegetation to themselves; hence, so far as present purposes are concerned, the obvious lesson is of a negative character—the what *not* to do in the case.

Too Much Rock and too much exposed are some among the chief of the glaring errors of rock garden construction to-day. They are common in the exhibition arena, and fast becoming so in gardens. That is to say, while the more grotesque errors of the so-called rock gardens of the past are being rapidly discouraged, there is still the danger of not a few rock gardens becoming all rock or a near approach thereto. This could never happen did the operator keep well in mind this fact—that the primary objects of a rock garden are that it be endowed with vegetable-life, that it be both an ornament and a thing of utility as well. Hence we must of necessity avoid the continuous wall-like structure or arrangement—the unyoked savagery of Nature—as unfitted to our purpose. Far too many artificial rock gardens err on the side of pretentiousness; they are too massive, too continuous, and, worst of all, are in this form forced under one's very nose—in other words, they are brought too near to the observer.

The Best Teachings of Nature in such matters—best because embracing a graceful contour with utility—are the teachings of our own hillsides. Here, in touch with the rolling bank—sculptured and fashioned by a thousand years—we see all that is good: the occasional boulder, the projecting ledge, the outcrop rock, nearly hidden from view it may be by the constantly moving *débris*, yet invariably disconnected, and ever suggestive of its possibilities for those who have eyes to see. It will be seen, too, that these rocks also invariably “lie to the bank,” arresting, as it were, the downward progress of seed and soil, and, while playing the part of receivers and retainers of moisture, also by their lie directing it at once to the roots of the plant. Hence their teaching value is enormous.

To fully comprehend all such teaching conveys is to grasp the first great fundamental principle of rock-building; to ignore it would be but to hopelessly flounder in the dark, and always with “rocks ahead.” In the end the best results are secured to our gardens by modifications of Nature's own, adapting them always to circumstance and environment. On the other hand, a mere slavish imitation of the unquarried rock masses would be wrong from every gardening point of view, and more particularly from the utilitarian standpoint. Such arrangements, however, are a thousandfold worse when the rocks are made to recede with step-like regularity and precision till a certain pinnacled summit crowns the whole and demonstrates both its crudity and inutility.

THE GRASS OF PARNASSUS. A BEAUTIFUL BOG PLANT, NATIVE OF BRITAIN.

The Disposition of the Rocks is, naturally, a matter of importance, though in the space at my disposal it cannot be here discussed in detail. Moreover, such things will of necessity have to bear some degree of proportion to the whole. For example, a rock and water garden of an acre or so growing out of a natural dell or declivity in the land would lend itself to a type of treatment impossible in the case of an elevated one-sided bank. In the former the rocks might with advantage crop out here and there in groups on the higher portions of the quite necessary grassed banks, and, intelligently treated with shrubs—*Yucca*, *Berberis*, *Cotoneaster*—would be in perfect harmony

with the whole. On the other hand, a similar arrangement in a rock garden of the banked style would be incongruous, and as such to be avoided. At the International Show at Chelsea in May last one of the most effective and pleasing of the many rock gardens was also one of the simplest. The stones or rocks employed were quite on the small size, and no attempt was made to make them appear what they were not. The rocks, comparatively, were few, and, being weathered and grey, were not glaring to the sight. They were buried, too, and, as in Nature, largely hidden from view, and their setting was such that the whole might have been taken from some hillside *en bloc*. It might have been there always, so restful and pleasing was it. In short, the whole secret of its success

lay in the disposition of the rocks themselves. In the case of larger boulders being employed, more building would be necessary; but even so there would be no occasion to lose sight of the principle involved. In the disposal of the rocks, one cannot refrain from touching upon some of

The Great Errors noticed from time to time. Elsewhere in this chapter I have directed attention to the lie of the rocks in Nature and commented on the value to the plant of this natural dip *into* the bank. Frequently, however, the exact opposite is seen, and where the rocks are of any size, the absurdity and futility of the setting are at once apparent. Stones or rocks having an inclination down the bank only rarely become garnished by moss, and the lesson is an obvious one. Such rocks generally are impossibles; that is to say, they collect neither *débris* nor soil, the moisture of dew and rain is immediately carried away, and, save for the covering of some long, trailing subject, would ever remain unfurnished. Obviously, then, they are wrong. Equally wrong, too, is the naturally-disposed rock whose toes persist in exposing themselves to view, thereby creating a vacuum which should not exist. In Nature not only is the base of the rock obscured from view, but the crumbling rock and *débris* are so banked up and associated therewith as to constitute it an ideal place for colonising the choicest of plants, which the informal outline will render into the happiest of groups. Here, indeed, the operator may copy Nature to the full, and in so doing will never err. E. H. JENKINS.

(To be continued.)

THE GRASS OF PARNASSUS.

(*PARNASSIA PALUSTRIS.*)

The Grass of Parnassus belongs to a small family of bog plants which have their head-quarters in the Himalayas. In this region there are some eight species to be found, including the largest member of the whole genus, *P. nubicola*. This species has been grown in gardens from time to

time, but is not a common plant. It is found at elevations ranging from 6,000 feet to 12,000 feet, and grows to a height of nearly two feet, with greenish white flowers. Several species are found in America, of which three are sometimes met with in cultivation. *P. asarifolia*, with Asarum-like leaves and greenish white flowers, is a distinct little plant. *P. caroliniana* is one of the best, growing 18 inches high, with large leaves and beautiful white flowers veined with green, sometimes $1\frac{1}{2}$ inches in diameter. *P. fimbriata*, of similar habit and stature, has white flowers, with a fringe of white hairs at the base of each petal. Our native Grass of Parnassus (*P. palustris*), a group of which is shown in the illustration on page 590, is a charming little bog plant which is well worthy of cultivation. In its natural habitats it has a very wide distribution, being spread over the temperate regions of the northern hemisphere. Throughout Northern Europe and Russian Asia it is found in bogs and moist heaths, but further South from the Alps to the Himalayas it becomes a mountain plant. It is a very easy plant to grow in boggy soil, and fresh seed germinates freely; but it is more at home in the more northern parts of this country. The stems are from 6 inches to 1 foot high, with a single sessile leaf below the middle, and bear a single white flower veined with green lines.

W. I.

THE GREENHOUSE.

THE WINTER TREATMENT OF GREENHOUSE FERNS.

BY far the most commonly grown of the extensive Maidenhair family is *Adiantum cuneatum*, for not only is it a general favourite for pot culture, both as good-sized specimens and as tiny plants in $2\frac{1}{2}$ -inch pots, but its delicately-divided fronds are largely employed for associating with the choicer kinds of cut flowers. It is usually referred to as a greenhouse kind (a most elastic term); but, as will naturally be expected of a native of Brazil, it requires a temperature above that of a structure from which frost is just excluded. Complaints are by no means infrequent of the fronds turning brown, especially during the winter months, and this is in most cases caused by the lowness of the temperature, which brings with it an excess of atmospheric moisture.

In order to keep this species of Maidenhair in good condition throughout the winter months, it will be, of course, essential to have good, well-rooted plants, furnished with firm, healthy fronds. To ensure this, overpotting must be avoided, and the amount of shading must not be carried to excess. Of course, shading is very essential during the summer months, but in autumn less is required, and for Ferns of this class, unless exceptional conditions prevail, no shading will be required from the end of September to the end of February. For the winter a light, buoyant, rather than a stagnant, atmosphere is to be preferred, and the temperature should range from 45° to 50° by night, rising from 50° to 60° by day; indeed, just such conditions as are essential to the production of greenhouse flowers at that season.

Throughout the winter the water supply must be carefully attended to; that is to say, the plants must never be allowed to suffer from want of water, but at the same time they should not be kept too wet. The browning of the fronds at this season

and the cause thereof have been alluded to, but insects and other pests sometimes give trouble. Slugs are well known as enemies of the Maidenhair Fern, and these are best sought for in the evening by artificial light, as they are difficult to detect in the daytime. It is not the large slug alone, that leaves such a conspicuous trail, which is to be feared; but tiny, dark-coloured ones that can hide almost anywhere are very destructive to Maidenhairs, and so are some very little snails, which often do a good deal of damage before their presence is detected. Cockroaches, woodlice and crickets are sometimes answerable for a good deal of damage, while to the uninitiated the ravages of a small, dark-coloured weevil often prove very puzzling, as the insects pursue their work of destruction by night, and directly a light appears they drop to the ground, where their dark colour renders them difficult of detection. By spreading a white sheet underneath the Ferns, these weevils may then be readily seen when they drop.

of 40° or thereabouts, rising 10° or so during the day, is maintained, there are many Ferns that may be grown. In such a structure Pelargoniums and other bedding plants can be safely wintered.

Prominent among Ferns that will do well under these cooler conditions may be mentioned *Adiantum aethiopicum*, *A. Capillus-veneris*, *A. decorum*, *A. formosum*, *Asplenium bulbiferum*, *A. Colensoi*, *A. bifforme*, *Cyrtomium falcatum* and varieties, *Davallia canariensis*, *D. Mariesii*, *D. bullata*, *Dicksonia antarctica*, *Doodia aspera*, several *Lastreas*, *Lygodium japonicum*, *Microlepia birta*, *Nephrodium molle* and its varieties, *Onychium japonicum*, *Osmunda palustris*, *Todea africana*, *Woodwardia orientalis*, *W. radicans*, and a great number of different forms of *Pteris*, especially the many garden forms of *P. cretica* and *P. serrulata*.

For a greenhouse without any artificial heat, perfectly hardy Ferns are the only kinds that can be grown and depended upon to give satisfaction. As so many hardy Ferns are deciduous, they may

A REMARKABLE ORCHID WITH MOTILE ORGANS (*CATASETUM SPLENDENS IMPERIALE*).

This Maidenhair, and, in fact, most of the others, for protective purposes be set closer together during the winter.

This Maidenhair, and, in fact, most of the others, push up a large number of new fronds about February, and as at that time a great many of the old ones are shabby, it is a very good plan to cut off all the old fronds just as the young ones make their appearance, and thus allow for their unchecked development. These young and succulent fronds are frequently affected by green fly, which may be destroyed by gently vaporising with the XL All Vaporiser. If repotting is needed, it should be done when the young fronds are about an inch in height. The foregoing remarks will apply to the great majority of greenhouse Ferns, of which some of the stronger-growing forms will, if the pots are well furnished with roots, require more water than the Maidenhairs.

The different crested and mossy forms of *Nephrolepis*, which have within the last few years become so popular, will succeed under the same conditions as advised for Maidenhair Ferns, while they will also thrive in a somewhat warmer structure. For a greenhouse where a winter night temperature

for protective purposes be set closer together during the winter.

H. P.

AN INTERESTING ORCHID.

THE Orchid family provides us with many remarkable plants, and of them the *Catasetums* are among the most singular. These plants are certainly more curious than beautiful. As a rule the flowers are of a greenish hue, with thickened, almost leathery segments. The flowers are most interesting, and provided much food for thought to the great naturalist Darwin, who made a special study of the fertilisation of Orchids. The chief interest in the flowers lies in the manner by which the pollen masses are ejected. A close inspection of the flowers illustrated will reveal the presence of two whitish horns seated within the perianth. When the flower is fully developed, these horns act as triggers, and, when touched, the pollen masses concealed within are ejected with considerable force. An insect visiting the flower is naturally startled by its welcome, and flies off with the pollen

masses adhering to it. Presumably the astonished insect does not profit by its experience, and later on pays a visit to a female flower, thereby bringing about cross-fertilisation. It was at one time thought that male and female flowers were produced only on different plants, and so dissimilar are the flowers in some instances that plants of the same species have even been placed in different genera. In recent years, however, it has been proved with plants under cultivation that a plant producing male flowers may on another occasion produce female flowers. The plant illustrated is a fine variety, with an almost black interior to the flowers, known as *Catasetum splendens Imperiale*.

"GARDENS FOR SMALL COUNTRY HOUSES."

This beautiful and comprehensive work brings home to one very forcibly the extraordinary

IN A GARDEN AT FOUR OAKS.

vigour of the modern movement in garden design, of which one of its authors must surely be looked upon as the pioneer. How short a time it seems since that delightful book, "Wood and Garden," appeared, followed by others equally refreshing and full of interest. To that series of works may be ascribed very largely the awakened love of garden design which makes the book we have before us possible.

The small garden is a thing which has practically only come into life during the last fifteen years, and is now so general as to have found a hold even in that stony ground mind of the "speculative builder." The serpent path and kidney-shaped "bedded-out" horror are things of the past—while the man or his wife who leave their garden to the whims of the hired man dare not confess it. It is acknowledged once more

that the house and garden should be part of the same scheme, and in consequence the designing of the garden has become very often the work of the architect. The present work can, of course, only give examples of a very few of the army of men who are doing splendid work all over the country, and it speaks well for the enthusiastic spirit of the profession that its members have so widely and successfully taken up this revived branch of their art. It is to such men, great architects as Philip Webb and Norman Shaw, that we must be grateful for this, and, in remembering them, associate Miss Jekyll's collaborator, Mr. Lawrence Weaver, to whom so much is owed for the magnificent work he has done, by criticism and explanation, in *Country Life* and elsewhere.

In the volume under review we have 308 illustrations, all of interest and of a standard we have learned to expect from this source. I mention these first as one is led to turn from page to page

with pure enjoyment before one can settle down quietly to read. Gardening, like domestic architecture, is suffering at the present time from a contagious disease, which takes the form of a persistent striving after "features," all of which must be antique, quaint and picturesque. Nothing is left alone; at every point and corner are details put together without rhyme or reason, regardless of locality and frequently of construction. And it is with this in view that much excellent advice should be sought in "Gardens for Small Country Houses"—and it is hoped will be taken. There is a great temptation to the unwary on looking through these fascinating pictures to take one bit here and one there and use them irrespective of the whole. Modern facility of transit is responsible for much that is wrong—it is no longer a matter of great difficulty or expense to obtain stone in a brick country or any other

material equally foreign, the difficulty being rather that of discerning that which truly belongs to the immediate neighbourhood.

There are twenty-one chapters, each dealing with a definite phase of garden design, and running through all is the note of that care and consideration which must be employed by those wishful of making their garden a place of peace and beauty. This end can never be reached by the indiscriminate choice of a series of features, no matter how beautiful they may be individually, if they do not form a part of one general scheme.

To quote one of the many things to be read and taken to heart: "When the site is a bare field, or any place without individuality, the designer has a free hand, but will be wise in choosing something that will be definite, so as to give that precious quality of character. It can only be created by simplicity of aim; by doing one thing at a time as well and distinctly as possible and so avoiding complexity and confusion."

The "free hand" with no lead given to it by natural difficulties to surmount is probably the most difficult of all problems to solve; it will, however, be surprising to the layman without previous experience how many possibilities and variations of levels will be discovered in an apparently flat, uninteresting piece of ground after it has been carefully surveyed and drawn out, the first essential step to the planning of a garden. Many gardeners are needlessly afraid of attempting to make a plan. Where a survey of the particular piece of ground is not obtainable from any other source, it can nearly always be traced out upon the 25-inch ordnance map, and the subsequent planning out to scale of the simple scheme correctly enough for ordinary small garden work is largely a matter of common-sense. The gift of visualising a scheme without the aid of a diagram to keep thoughts and ideas coherent is a very rare one. The many excellent plans and diagrams given in this book are so clearly submitted to the reader that they will do much to teach the necessary part of the work. The instructions given for the building of dry walling leave nothing to be desired. In dry brick walling stability is difficult to attain, and I have found it well to build the bottom and top three or four courses in mortar. This adds very considerably to the strength of the wall without noticeably differing from the rest if the joints are well raked out. Where a "battering" retaining wall of any considerable height is to be built, it adds to the effect and convenience to break the slope halfway up with a narrow pathway, say, 14 inches to 18 inches wide, reached by steps at intervals of the same width. The one I have in mind was originally built as a Strawberry-bed, "headers" being left out every third course about 18 inches apart—flowers now take the place of the Strawberry plants and the effect is delightful. I was left puzzled by the dictum on page 249: "In every case the rock garden should be as far as possible from the dwelling-house," remembering with pleasure, as I do, more than one entirely satisfactory rock garden in the closest proximity to the house overlooked directly from sitting-room windows. But this and a depreciating reference to "random walling," with which I do not agree, are small matters.

The book is one of those rare and happy works which will be a valuable text-book and reference on all questions of garden design, both for professionals and amateurs, and a joy to anyone who wishes to spend a quiet hour in a garden atmosphere.

MAXWELL AYRTON.

GARDENING FOR BEGINNERS.

FRUIT TREES IN TOWN GARDENS.

IN this article my plea is not for Roses, although I grow them, but for a branch of gardening which the town man with a garden seems somewhat reluctant to take up. He can grow Roses, Sweet Peas, Carnations and many other beauties of the floral world up to exhibition standard, perhaps; but if he were told that certain varieties of Apples and Pears could also be grown, and that these might reasonably be expected to far exceed in size and quality the fruits usually seen on old trees in country orchards, he would probably doubt it. Yet such is the fact. All my trees are grown in a town garden, which is nearly a mile from the nearest open country, and receives its full share of the usual smoky atmosphere of a large town. The Apple trees are grown as bushes on the Paradise stock, and the Pear is also a bush on the Quince.

Eight years' experience has shown me that the trees, in order to grow and bear well, must be given as much space to themselves as possible (at least 10 feet to 12 feet between them). If this is not done, they fall an easy prey to insect pests, and become "drawn" in the struggle for existence in much the same way as a box of seedlings which has been sown too thickly.

Manuring, though desirable, does not seem to be of such importance in a town as keeping the soil sweet and in good condition. Insect pests are quite easily kept at bay with a good syringe and with no more costly insecticide than clear water. This may seem a rather bold assertion; but I have frequently found, to my very great satisfaction, that American blight and other insects which live in colonies gain no foothold among the trees when a good syringing of the leaves and stems was given once or twice a week and using water only.

I have also found that it is a mistake to grow other things in the space occupied by the trees. One of the easiest ways of keeping the soil open to atmospheric influences is by hoeing, and this cannot be done effectively if the ground is occupied by other plants.

Worcester Pearmain is a most reliable Apple to plant anywhere. It seems as natural to look for Apples on a bush of this variety as it is to look for berries in the hedgerows in autumn. Lane's Prince Albert is also a sure cropper, and, given only the coolest room available in an ordinary dwelling-house, the fruits will keep well till spring. The ideal conditions for Ribston Pippin were provided by the exceptional heat and sunshine of last year. The crop this year, consequently, was much larger than might have been expected. Stirling Castle is a variety which flowers abundantly,

and usually sets a very large number of fruits. The growth of the tree, indeed, will be retarded unless thinning is resorted to. Irish Peach and Newton Wonder also do well with me. Both Pears and Apples this year flowered very much earlier than usual in this district, but the former suffered somewhat from the frosts of mid-April.

3, Ash Grove, Hull. W. H. BOLTON.

A USEFUL RACE OF DECORATIVE CHRYSANTHEMUMS.

THERE is no better type of Chrysanthemum for the amateur to cultivate than the decorative. Dwarf,

but there are more recent acquisitions that have originated as sports from it. Notably there is White Caprice, or White Cap as it is better known both in gardens and in the market. A fine bushy specimen, as broad as it is long, is illustrated on this page. Here a dwarf plant is depicted at its best, and provides a good idea of what the amateur should aim at in cultivating this useful race of the Chrysanthemum. There is a more recent variety, known as Yellow Cap or Golden Cap, of precisely similar habit, and one which flowers with equal freedom, producing a mass of rich golden colour. The last-named variety was introduced a year ago, having occurred simultaneously as a sport both with Messrs. Wells and Co. at Merstham and with Messrs. James Veitch and Sons in their Feltham nurseries. Chrysanthemum sports, it should be added, have a peculiar way of occurring in different places in the same season.

A WELL-GROWN SPECIMEN PLANT OF CHRYSANTHEMUM WHITE CAP.

IS SAWDUST INJURIOUS IN HORTICULTURE?

THERE seems to be a widespread prejudice against sawdust or, at any rate, contempt for it when used as a manure. American gardeners are like English ones in this respect, it seems, and so three years ago they started experiments to try to justify their point of view. These have been continued for three years on a large scale on greenhouse plants chosen for the purpose. Perhaps this was because they are more delicate than outdoor plants, or because conditions could be better controlled. Anyhow, the results were somewhat extraordinary, and do away with any ground for suspicion, it would seem, against this cleanly material. It cannot be denied, however, that sawdust is nearly useless as a source of plant food, and therefore it is matter for surprise that when an average was struck for the three years, sawdust actually came out top and gave slightly more blooms than the other litter which was tested against it. This was straw or

bushy plants make a magnificent show in the greenhouse or conservatory at this time of year, and they may be cultivated by the veriest tyro. Such plants require occasional stopping in the growing season until the end of July to induce uniform and well-balanced growth. Disbudding is likewise necessary before the flower-buds show colour, while throughout the cultivation, from the time of the first potting until the flowering, each plant needs plenty of room from its neighbour in order to make the dwarf, bushy growth that is so very desirable. Of the varieties suitable for the formation of dwarf flowering plants, it is questionable if any are better qualified than either the time-honoured Caprice du Printemps or any one of its many varieties. This is one of the oldest varieties in cultivation,

chopped Maize stalks, superior stuff as regards plant food, surely, to sawdust. Cow-manure was chosen in each case, and was used by itself as a further source of comparison without any litter at all. Roses, Chrysanthemums, Sweet Peas and Carnations, manure-loving plants, were the ones chosen, and we learn that no harmful effect at all could be traced to the use of sawdust. This is curious. Can it be due to the slightly antiseptic properties of sawdust, which kept injurious bacteria at bay? Pyroligneous acid may be of use in this way. It could not have contributed even to the humus of the ground in the same way as the other litter, for it did not decay before use, and possibly it was this comparative absence of fermentation that effected the results mentioned. T.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Chrysanthemums.—In common with other hardy flowers, these may now be cut down almost level with the ground. The stools will go through the winter unharmed; but if it is desired to propagate from them, I prefer to lift the stools and place them under a light in a cold frame in soil. Spring cuttings as they form may be easily removed and placed in pots or boxes to strike.

Oriental Poppies.—These are charming plants for the herbaceous borders, and are particularly suitable for shallow soils and otherwise dry borders. Planting may be done at once.

Christmas Roses (*Helleborus niger*).—The plants will soon be throwing up their blooms, and if these are wanted in advance of those out of doors, a few clumps may be lifted and placed in quite a cool house and the roots covered with soil, or hand-lights may be placed over the clumps, which will prevent the blooms from getting splashed with the rain and dirt.

The Rock Garden.

Planting Shrubs.—Any alterations or additions to the shrub-life of the rock garden may now be successfully undertaken when the weather is open. Shrubs play an important part in furnishing and providing backgrounds and shelter for some of the less hardy plants that find a home there. These are apt to become too large, however, and, if possible, only include those of slow growth and generally of spreading, dwarfier habit.

Hardy Heaths.—The many varieties of *Calluna vulgaris* and *Ericas* form excellent subjects for providing a touch of colour at various seasons, while their evergreen foliage is at all times attractive. The ground for these should be devoid of lime and well enriched with plenty of decaying leaves or peaty growth, when they will form excellent subjects. A garden devoted to these and planted in irregularly-shaped beds is a feature where it can be carried out.

Plants Under Glass.

Violets.—The plants in frames or heated pits for providing winter blooms must be kept as cool and freely ventilated as possible, and whenever the weather is mild enough, remove the light entirely. Aerate the surface soil between the plants, and if they are well established, give them a sprinkling of Clay's Fertilizer or some other suitable plant food and water in. Watering should be carried out on a mild day before noon, and the lights well tilted so that the growth dries before night. Remove any runners from the plants.

Violets in Pots.—These are an attraction to the greenhouse, thrive well in an unheated structure, and may be utilised for room decoration. Give the plants a little manurial assistance, and see that they are kept supplied with sufficient moisture.

The Hardy Fruit Garden.

Nuts.—There are many gardens where these could be planted with advantage, and if a little attention is given them, excellent crops are produced from quite convenient-sized bushes. Both Filberts and Cobs, whichever are preferable, may be planted in variety, and where both are included, finer crops are obtained, due to better pollination, I think. Choose well-drained soil, and not too heavy for preference, a sunny bank suiting them admirably, or they may be planted in the orchard in an open position. Keep the bushes free from suckers—these, if cut out during the winter, make excellent supports for plants when tied up in different lengths and placed on one side—and avoid overcrowding of the growths. Some people, when the female flowers are open, place or shake over them the catkins of the common Hazel.

Raspberries.—The quarters of this crop may be cleaned over now and any superfluous suckers taken up, and, if necessary, new plantations made on well-prepared ground that has been well enriched with manure. Raspberries should be planted in the most convenient manner, so that protection can easily be afforded when in fruit. This is best done either by planting in rows and training the growths in a slanting direction to wires stretched from stout posts, or by planting in clumps at intervals

and the growths tied up to a stout stake. The former has much to recommend it, and when duly thinned, equalised out and tied up, splendid crops may be obtained. Give a good mulching of decayed manure over the roots.

Fruits Under Glass.

Cleansing of Fruit-houses.—In addition to the thorough washing of fruit-houses, particularly the inside of both woodwork and glass, it is of paramount importance that the walls be well lime-washed or treated, as the case may be, so that any insect pests that may be lurking in the crevices are destroyed. The hot-water pipes will be considerably improved in appearance by a coat of black, nothing being better than lampblack and oil; this, though perhaps not quite so lustrous in appearance, does not give off offensive smells.

The Kitchen Garden.

Early Peas.—Where ways and means exist, excellent pods of Peas may be obtained in May by sowing seeds now in large pots or in cool houses in borders. Use a good loamy compost, to which add some Mushroom-bed manure and bone-meal, and see that the pots are well cleaned and drained. Nine-inch or 10-inch are the most suitable sizes, and for a start only half fill with the mixture. Sow as thick again as it is intended the plants shall remain, and place in a cold frame to germinate. Coddling must never be permitted at any time, but give plenty of air, and when germinated thin out to five or six plants and place a neat stick to each.

Spinach.—This crop is looking well this year, and the latest sowings have made good progress. Keep the soil between the rows hoed with the Dutch hoe, and give a sprinkling of soot. Remove by hand any weeds between the plants. See that the seedlings do not become overcrowded, but avoid thinning too severely.

Frames containing Lettuce, Endive and Parsley should be freely aired during mild, open weather, but have plenty of protecting material handy in the event of frost.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Frame Protection.—It is probable the winter may be a severe one, and though many of the plants passing the winter are newly-rooted cuttings and hardy, long-continued frosts are not beneficial. Dry straw placed above the inmates of cold frames I find a very efficient method of protection, the glazed lights keeping the straw dry and always frost-proof, while even if a foot thick it does not wholly exclude light.

In Case of Frost.—The inexperienced are very apt to admit air to frames after removing coverings on the appearance of a change after frost. This should never be done until the signs of a permanent change are unmistakable, vicissitudes of temperature being more harmful than a very low one; nor should the coverings be removed too soon. Even in frosts of only a few days' duration it is best to let the coverings remain all the time.

Frost-bitten Plants.—Some—*Calceolaria*, for instance—may be so severely frozen as to be killed to the soil-level. The plan to pursue is to keep the plants dry till spring-like weather comes, when, if the soil is dry, as it ought to be, growth will in all probability be pushed from underneath, the soil being a fairly good protective medium. *Calceolaria amplexicaulis*, now so deservedly popular, in no case should be left in cold frames over the winter.

Tender Plants.—*Ageratums*, *Lobelias* and some others are somewhat difficult to winter safely. The proper treatment is to keep them gently moving, for if kept too cold or too wet they die. If too hot they sometimes die, and, if not, become so weak as to be of slight utility for cutting purposes in spring. *Geraniums* should be kept cool and perfectly dry, but not roasted above the hot-water pipes, as we sometimes see them.

The Shrubberies.

Leaves.—The foliage of most trees and shrubs fell much earlier than usual this year, and a month

ago we had the shrubberies roughly cleaned, also the lawns. In weather unsuitable for ground-work they should have a final cleaning for the season, preserving the dead leaves for top-dressings, manuring or leaf-soil. The opportunity may be taken to prune those shrubs needing thinning, cutting out dead wood and removing branches broken by autumn gales.

Surface-dressing.—After a time shrubs become weakened and unhealthy for want of nourishment. Material from the compost heap or decayed vegetable mould has a beneficial effect if spread 4 inches to 6 inches thick above the rooting space. Frosty weather should be taken advantage of to wheel or cart the material on to the ground.

Coloured Shoots.—The value of these in winter is very great. The Rubi afford a good example. The present year's growth alone should be left in pruning, when the effect will be considerably improved. One of the best is *Rubus phoenicolasius*, which is a rich brown, shining in sunshine, but always effective. The white-barked species are also very telling. Dogwoods, *Prunus cerasifera*, *Corchorus japonicus*, *Ribes*, *Leycesteria* and *Deutzia* afford good material for decoration, but the shrubs which provide the shoots should not be severely thinned, else they lose their effectiveness.

The Fruit-Houses.

Vines.—Where Grapes are wanted in May and June, the viney should now be closed down and the atmosphere kept pleasantly soft without being warm. If part of the roots are outside, means to protect them from cold and too much wet should be taken, though the advantages of having all the roots inside and under complete control are so great that early vineeries would be much better arranged in the latter way.

Lady Downe's.—The very late Grapes should now be perfectly matured, and while they hang on the Vines the vineeries should be kept perfectly dry and the temperature as steady as possible, ranging about 45° to 48°. Alicantes are at their best now, and are apt to depreciate in the course of a few weeks, though they keep in good condition for a long time when bottled.

Peaches.—If the foliage has not all fallen, it may be lightly switched with a Birch broom, moving it in the direction of the growth, when most of it will come off. Any left on the tips of the shoots may be taken as evidence of unripened wood, which should be removed by pruning. If the border inclines to dryness, apply water—manure-water preferably—in moderate quantities, bud-dropping being attributable to winter drying of the soil. Ventilate as much as the weather will permit.

The Plant-Houses.

Begonia Gloire de Lorraine.—Plants in full flower will do quite well in a cool house not over-ventilated. The flowers stand much longer in such a structure than in a stove, where later batches should still be kept. It is a capital house plant, and will stand seemingly unaffected for a few weeks, but it is far preferable to change plants at frequent intervals. They require frequent watering in hot apartments.

Cyclamen.—Young plants have been rather troubled with mite, which deformed some of the flowers. Repeated applications of nicotine, vaporised, are essential whenever this appears, and the centres where the buds cluster, as a further preventive, may be dusted with Tobacco powder.

Primula malacoides.—Late-sown batches now throwing flowers should be afforded just a little warmth, else they are very slow in coming on, and the foliage and flowers seem to be somewhat less sweet when in a perfectly cool structure than in one slightly warmer. Well-diluted manure-water is of much value, and an occasional pinch of sulphate of ammonia, but only a pinch, has a very gratifying effect.

Primula obconica gigantea.—This plant is now so improved as to be indispensable alike as a decorative pot plant and as a cut flower. The colours are perfect, and the flowers have the additional advantage of remaining fresh for weeks—three at least—in a cut state. The plants must be kept slowly growing all along, and be treated to manure from time to time to keep the foliage a deep green.

R. P. BROTHERSTON,
Tynninghame, Prestonkirk, N.B.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

TO TRANSPLANT AZALEAS AND WATER LILIES (Hex).—Azaleas may be transplanted at any time between the present and the end of March, when the weather is open; but do not undertake the work when there is any sign of frost. Be careful to plant firmly, and keep the upper roots near the surface of the soil. Water Lilies may be planted during February and March. A good time is when the young leaves are showing signs of starting into growth. Plant in baskets, using loamy soil, unless the water can be let out of the pond. If that can be done, mounds of loam may be formed and the Water Lilies be planted in the ordinary way. Baskets are better than casks for the purpose.

HERBACEOUS BORDER GROUPING (M. S. W.).—The really effective way of grouping in such a case is that of arranging a number of plants over a rather large area of ground, each group of about three feet across. For example, taking a group of Michaelmas Daisies or of Phloxes, you might arrange six or nine of the latter and a dozen of the former, and more or less of other plants, according to their habit of growth and root spread. In this way your 8-feet-wide border might contain, roughly, three lines of groups in the longitudinal section, irrespective of any marginal plants that might be used, the third, or front, group being somewhat smaller than the rest. All the groups should be of irregular outline and alternate one with the other. By this arrangement a maximum display is obtained with a minimum of space. Of such plants as Phloxes, Heleniums, Pyrethrums, Kniphofias, Sunflowers and Michaelmas Daisies, small plants comparatively only should be used.

PLANTING HERBACEOUS BORDER (G. B. R.).—A border of 8 feet wide might, for convenience sake, be roughly divided into three informal lines of groups running longitudinally the whole length of the border. To each of the groups in the two back lines a space of 3 feet each should be allotted, thus leaving a 2 feet front for smaller groups of plants. In the back lines the groups should alternate one with the other, which is not only convenient for purposes of display, but as a ground covering idea has much to commend it. In this way Sunflowers, Delphiniums, Hollyhocks, Michaelmas Daisies, perennial Peas, Heleniums and other plants of like stature would appear in the background, with Phloxes, in several distinct shades, Peonies, Gaillardias, Campanulas, Anchusa, Flag and other Irises, dwarfier Delphiniums, Papaver, Scabiosa, Lilies of half-a-dozen sorts and the like in the second row. In the front line of groups, which, if possible, might also extend as a margin, Pyrethrums, Columbines, Aster Amellus in variety, Campanula carpatica, Heucheras, Primulas, Statice, Rudbeckia, Stokesia, Pentstemons, Lychnia Viscaria fl.-pl., Geums and much besides could be utilised, the immediate front being confined to Aubrietias, alpine Phloxes, Mossy and other Saxifrages, Pinks, Hepaticas, Adonis and dwarfier Harebell, Campanulas pusilla, p. Miss Willmott, pulla, pulloides G. F. Wilson and so forth. In planting, three or five examples—in some instances less—would constitute a group, save for the front, where a carpeting arrangement would be best. To secure a good effective display, such a border should be arranged from a working plan so as to avoid flashing.

THE GREENHOUSE.

VENTILATING A GREENHOUSE (M. E. L.).—You ask whether the ventilators of the cool greenhouse should be opened indiscriminately in all weathers? Our answer is that it depends upon the season of the year; but during the summer months a certain amount of air should always be left on. The Geranium and Heliotrope, which do badly, both do well out of doors during the summer; hence it is evident that their weakened state and poor condition is caused by an insufficient amount of air and light. If you attempt to grow them under the shade of the Vine, a good deal of the trouble may be accounted for in this way. Much of the non-success in plant-growing indoors is caused by coddling them too much, perhaps allowing the house to become too hot and dry, and then giving a lot of air all at once so that the plants get a decided shock.

ABOUT CHRYSANTHEMUM BUDS (G. D. R.).—In a dull, cold summer, such as we have experienced this year, many varieties of Chrysanthemums, when treated for the production of second-crown buds, will bear terminals. The very hot period earlier in the season prematurely ripened the wood of many varieties, and these persistently showed flower-buds in the summer-time. You may treat the plants in a similar way for several years, and if the seasons are normal the proper buds will form. We presume you pinched (stopped) the shoots to produce the second crowns. If not, there would naturally be the three breaks, the break, the first crown, and then the terminal with the surrounding buds.

ROSE GARDEN.

WICHURAIANA ROSES TO PLANT (H. E.).—Both Leontine Gervaise and René André are thoroughly good in every way, but they resemble each other rather much. If you desire two quite distinct, we would recommend Alberic Barbier and Leontine Gervaise. The rugosas Conrad F. Meyer and Rose à parfum de l'Hay are both very good.

WICHURAIANA ROSES FOR TOWN CULTURE (H. E.).—There is hardly enough distinction between Delight and Hiawatha. We should advise you to have Excelsa, and of your other list select Leontine Gervaise, Gardenia instead of Shower of Gold, and Elise Robichon. These are very lovely and all distinct, and would stand a rather bad atmosphere the best.

PREPARING BEDS FOR ROSES (F. D. J.).—We advise you to have the proposed beds dug out to a depth of 3 feet. Put on one side the top soil if it is of a loamy nature, and keep that which is very gravelly by itself. The beds should then be refilled with some good top soil, either taken from another part of the garden, preferably where it has been enriched with manure for vegetables, or imported from some dealer in loam in your neighbourhood. As the new soil is put into the beds, mix with it that removed from the surface, and also some well-rotted manure at the rate of one part of manure to two parts of soil. You should also add to the soil, about two feet down, a dressing of basic slag at the rate of 6oz. per square yard, and just fork this into the soil. Fill the bed about one foot higher than the ground-level, in order to enable it to settle down to its correct level. You can plant the Roses after the beds have been prepared two or three weeks, choosing a fine day for the work, and as you plant each Rose bush or standard, scatter a handful of bone-flour around the plant and just beneath the surface soil. Sweet Peas will also thrive well in soil thus prepared. Sometimes soil, "top-spit" it is called, may be purchased from builders where new houses are being erected. That from a meadow would be ideal material, and if you have the turf, put this grass downwards into the beds.

KITCHEN GARDEN.

INJURY TO CABBAGES (Enquirer).—The plants are attacked and destroyed by Cabbage-root maggots. Try nitrate of soda and Vaporite or some other soil fumigant; but the pest often disappears without any apparent reason.

CELERY LEAVES DISEASED (E. G. and Others).—The Celery is attacked by the fungus Septoria petroselinii A. Pil. Diseased foliage should be removed and the healthy parts sprayed with Bordeaux mixture or potassium sulphide. None of the refuse from the Celery should be put on the rubbish-heap, but it should be burned. Next season grow the plants as far as possible from the part where they are now growing. It is a disease which is liable to spread exceedingly quickly.

MISCELLANEOUS.

VARIOUS QUESTIONS (Mauby).—1. The maiden loam is best stacked in the open while it is weathering. It would be apt to become too dry in a shed. After it is fit for use it may be kept for a time under shelter, so that it may be in a friable condition when wanted. 2. Both paraffin and lubricating oil would be likely to interfere with the proper decay of the refuse, such as goes on in a heap and is necessary before plants can make any use of the stuffs locked up in them. It is, therefore, very undesirable for these to find their way into the refuse heap.

NAMES OF PLANTS.—Dolphin.—Linaria repens. There are many species of Linaria, and L. repens itself varies to a certain extent.—J. J.—Tolmie Menziesii.—F. J., Gloucestershire.—Yes; Kniphofia aloides.—Iris.—Kniphofia Uvaria grandiflora and K. Saundersi are both good and reliable. Flowering season July till September.—Coningsby Hall.—Juglans nigra (Black Walnut).

NAMES OF FRUIT.—J. K.—1, Doyenné du Comice; 2, Marie Louise d'Uccle; Apple Hollandbury.—J. P.—Seedling Apple, a very good cooking variety, but not superior to varieties already in existence.—H. W. C.—1, Beurré Goubaux; 2, Bishop's Thumb.—Woodgate.—1, General Toldken; 2, Josephine de Malines; 3 and 4, Hawthornden, 5, Emperor Alexander.—G. H.—Berwick, Sussex.—1, Cornish Aromatic; 2, Cox's Orange Pippin; 3, Beurré Dumont; 4, Josephine de Malines.—E. M., Richmond.—Rosemary Russet.—G. W. E.—1, Peasgood's Nonsuch; 2, Rambour Franc; 3, Blenheim Orange, well coloured; Pear King Edward.—J. K., Ireland.—Apples: 1, Wintonhill Fillsbark; 2, Flanders Pippin; 3, Gloria Mundi; 4, Ard-Cairn Russet; 5, Wellington Pears: 1, Beurré Biel; 2, Verulam.—E. M. A.—See next week's issue.—C. W. Kitson.—Sops o' Wine.

SOCIETIES.

NATIONAL CHRYSANTHEMUM SOCIETY.

An important meeting of the floral committee of the National Chrysanthemum Society was held at Essex Hall, Strand, London, W.C., on Monday, November 11, at three o'clock in the afternoon. There was a good attendance of members of this committee, and no fewer than forty-three new varieties of Chrysanthemums were submitted for adjudication. A high standard of quality was observed in making the awards, many really good things being passed over. The following varieties gained recognition.

FIRST-CLASS CERTIFICATES.

Enchantress.—A large and refined Japanese bloom of exhibition standard. The petals are long and of medium breadth, twisting and slightly curling, and building a bloom of drooping form. Colour, white, suffused pink at the ends. Late blooms are much better coloured.

Mrs. W. T. Smith.—This is a large, deeply-built incurved Japanese flower of beautiful form and good quality, having broad petals reflexing and incurving at the ends: white. From Mr. A. Smith, Covent Gardens, Rochampton.

Mrs. W. E. Tricker.—Another large, solidly-built incurved Japanese bloom, having fairly broad petals, neatly incurving and of deep build. Colour, deep blush.

Mrs. G. W. C. Drexel.—Although shown in varying form, this is a monster Japanese flower of great refinement. The petals are very long and of medium width, twisting and curling and incurving at the ends, and building a graceful flower of drooping form. Colour, silvery pink. From Messrs. W. Wells and Co., Limited.

Mme. Depree.—This variety was classified as an incurved Chrysanthemum, although the long, pointed petals of medium width incurve in a fashion rather like a Japanese. It is a large flower for this section, and is regarded by market-growers with much favour. Colour, creamy white, tinted blush. From Mr. H. W. Thorp, Worthing, Sussex.

Mrs. J. G. Day.—A beautiful Japanese variety of good quality. The petals are fairly broad and long, pleasingly reflexing and incurving at the tips, building a flower of drooping form. Colour, a very lovely tone of golden amber. Shown by Messrs. H. J. Jones' Nurseries, Limited, Ryecroft Nursery, Lewisham, S.E.

June.—One of the most remarkable of the large-flowered singles extant. The blooms are from 7 inches to 8 inches in diameter, and the long, very broad petals are disposed in most even fashion round a nicely-proportioned disc. There are about three rows of petals. Colour, deep rose, tipped white, with narrow white zone round yellow disc.

Thorp's Amaranth.—A most attractive market variety of Japanese origin. The bloom is of fairly even form, having fairly broad petals neatly reflexing. Colour, deep rosy amaranth, with silvery reverse. The flowers are about six inches in diameter. From Mr. R. W. Thorp.

Ivor Grant.—A superbly fine medium-flowered single having a double row of broad florets very evenly disposed, building an ideal bloom of its kind. Colour, rose pink, with white zone round yellow disc. From Mr. G. Mileham, Emlay House Gardens, Leatherhead, Surrey.

Ravena.—This is a very distinct large-flowered single, having two rows of petals of medium breadth evenly disposed. Colour, chestnut crimson, with yellow zone round deeper yellow disc. From Messrs. Cragg, Harrison and Cragg, Heston, Hounslow.

Bronze Beauty.—A splendid medium to large sized single, having about three rows of petals of good breadth that build a bloom of good form. Colour, rich orange bronze, with yellow zone round disc.

Ethel Mortimer.—Another grand, large-flowered single of superb quality. The blooms are fully 4 inches in diameter, and have from three to four rows of fairly broad petals that slightly recurve in even character and build a charming exhibition or market variety. Colour, clear golden yellow. These two novelties were shown by Mr. Philip Ladds, Swanley Junction, Kent.

COMMENDED.

Cynthia.—For market uses and for bold decorative displays this new Japanese variety is noteworthy. The flowers are about six inches in diameter, the petals being rather narrow, but of good length. Colour, a lovely tone of rich crimson amaranth. It is a flower in the same category as R. F. Felton and Cranford Pink. From Mr. Walter Jinks, Thames Ditton.

Miss Mary Oller.—This is a dainty little single classified as medium to small flowered, of an attractive character, being about three inches in diameter and having three rows of rather narrow petals neatly disposed. Colour, bright yellow. From Messrs. W. Wells and Co., Limited.

READING GARDENERS' ASSOCIATION.

The usual fortnightly meeting was held in the Abbey Hall (by permission of Messrs. Sutton and Sons) on the 4th inst. The president (Mr. F. B. Parfitt, J.P.) occupied the chair, and there was a large attendance, which included the vice-president (Mr. Leonard Sutton). The lecturer announced for the evening was a delegate from the kindred society at Bristol, but at the last moment he was unfortunately prevented from journeying to Reading. His place was admirably filled by a brother Bristolian, Mr. I. House, who is always welcomed by the Reading Association. The subject was "Hardy Perennials." In the first part of his paper Mr. House defined the term "hardy perennial herbaceous plants," and expressed regret that complicity of show schedules were not clear in their stipulations

Bulbous plants should not, in his opinion, be admissible in a class for hardy herbaceous plants, neither should any of doubtful hardiness, nor others treated as greenhouse plants, for the purposes of competitive exhibition. He instanced plants which were not easily propagated, among others commending *Ostrowia magnifica* and giving his experience with it. Another list comprised those which were not generally successful, as *Romneya Coulteri*, supplementing it with cultural details. Mr. House also gave the names of a number of the newer and finer forms of better-known plants, as *Phloxes*, *Pyrethrums* and *Montbretias*. In another section of his paper he gave the names of plants which were undesirable occupants of the herbaceous border on account of their predatory habits. He advised his audience as to the kinds of plants which were best left undisturbed for several years, as the forms of *Aster Amellus*, *Dictamnus Fraxinella* and *Paeonies*, and enumerated others which were better for annual or biennial replanting. Mr. G. Carter, gardener to Mr. S. Griffith, Gordon Lodge, exhibited a very pretty group of *Primula Norton's Giant Pink*, for which he was awarded a certificate for cultural skill.

SANDHURST, YATELEY AND DISTRICT GARDENERS' ASSOCIATION.

THE fourth meeting of the winter session was held in the Church Schools, Sandhurst, on November 5. Mr. F. W. Benham presided over a moderate attendance, when Mr. J. Evans, The Gardens, Snapraills, Sandhurst, gave a most interesting paper on "Roses," dealing fully with the preparation of the ground, planting and pruning. A good list of the best varieties in the various sections was given. An excellent discussion followed, in which many points of interest were raised. At the close a hearty vote of thanks was accorded Mr. Evans for his paper.

WARGRAVE GARDENERS' ASSOCIATION.

THE eleventh annual show (non-competitive) organised by this society in aid of the Royal Gardeners' Benevolent Fund was held in the Woodlyffe Hall, Wargrave, on Wednesday, November 6. It proved very successful, both as regards the quality of the exhibits and the interest taken in the show by the general public, the hall being well filled, during the evening especially. The staging arrangements were superintended by Mr. W. Bazeley, assisted by a strong committee. Instrumental and vocal music was provided during the afternoon and evening, and greatly added to the enjoyment of the visitors to the show. The exhibits were arranged on three tables running the whole length of the hall, besides which the permanent stage was also used for small groups. The ladies and gentlemen who sent exhibits were as follows, the gardeners' names being in parentheses: Sir Charles Henry, Bart., M.P. (gardener, Mr. R. Doe), Mr. A. B. Gill (Mr. Pope), Captain Coleridge (Mr. W. H. Scott), Mrs. Rhodes (Mr. T. Haskett), Mr. G. Stanton, Mrs. Groves (Mr. A. Mackenzie), Mr. E. C. Hansen (Mr. H. Atteley), Mr. Martin J. Sutton (Mr. H. Clark), Mr. G. C. Davies (Mr. T. Tunbridge), Mr. Razeley, Twyford Nurseries; Mr. H. C. Bond (Mr. R. Perry), Mr. R. C. Harrison (Mr. J. A. Hall), Major Bulkeley, D.S.O. (Mr. W. Massey), and the Wargrave Plant Farm, Limited (manager, Mr. H. Richardson).

LIVERPOOL HORTICULTURAL ASSOCIATION.

THIS society held its thirty-third autumn exhibition in the Corn Exchange on the 13th and 14th inst., which fully upheld the high traditions of the city which gave birth to the large exhibition Chrysanthemum. The show under review is credited as being the best autumn exhibition yet held.

Cut blooms possibly form the popular section, which were shown in quantity, and, what is generally recorded of Liverpool exhibitors, no inferior specimens were to be seen. The chief class was won by Mr. C. Goves, gardener to Sir Gilbert Greenall, Bart., Warrington, in which he secured the handsome silver challenge vase, the gift of Sir W. H. Tate, Bart. The thirty-six flowers—eighteen Japanese and eighteen incurved blooms—were greatly admired, and to make a selection we might give: Japanese, William Turner, which secured the National Chrysanthemum Society's certificate for the best Japanese in the show; F. S. Vallis, President Viger, Lady Talbot, Hon. Mrs. Lapes and A. T. Miller: incurved, Mrs. G. Denyer, G. F. Evans, Marjorie Shields, Romance, Mrs. R. H. Hall and others. This exhibitor and Mr. J. Clark, gardener to Mrs. Clarke, Allerton Hall, had many remarkable incurved blooms. The second prize-winner in the "Cup" class, Mr. G. Haigh, gardener to Sir W. H. Tate, Bart., Woolton, had many beautiful incurved blooms. His *Buttercup*, noted for its form, colour and size, easily secured the National Chrysanthemum Society's certificate as the best incurved in the show. This exhibitor had many fine blooms, staged in vases, which many people prefer to the more formal style of arrangement in boxes or on stands. A feature of the exhibition were the sterling exhibits of single cut Chrysanthemums set up in vases with nine blooms in each vase. This section has steadily improved, but the present exhibits easily surpassed all previous efforts. To Mr. Loo Thomson, an enthusiastic amateur of Forbury, much credit is due for his superb display. The varieties that have met with such general approval are *Edith Pagram*, *Snowflake*, *Crimson King* and *Bronze Pagram*. The blooms measure from 5 inches to 6 inches in diameter, and are well adapted for a display in a large room or hall. Mr. G. Haigh and Mr. G. Eaton, gardener to W. Tod, Esq., Allerton, also staged splendid exhibits.

WEST OF ENGLAND CHRYSANTHEMUM SOCIETY.

THIS society opened its annual show in the Guildhall, Plymouth, on Tuesday, November 12. The exhibition proved to be one of the most successful and attractive that have ever been held in the town. This year the Earl of Morley has become the president of the society. The entries were more numerous than in late years, and the competition was very close. The judges often experienced considerable difficulty in arriving at their awards.

The cut blooms were well shown and very numerous. In the first class, for twenty-four Japanese blooms, the first prize was won by Lady Buller. In her stand were good examples of W. Turner, Rose Pockett, Miss L. Baker, F. S. Vallis and Lady Talbot. The same exhibitor also won first prizes for eighteen Japanese and for six Japanese.

In the class for twelve Japanese, the first prize was won by Mr. T. B. Bradshaw.

In the class for twelve vases of single Chrysanthemums, the first prize was also won by Mr. T. B. Bradshaw; but he was beaten for the silver-gilt medal by the winner of the class for single Chrysanthemums in the local class, Mrs. Bainbridge.

The first prize for a group of stove and greenhouse plants was won by Mrs. Bainbridge with a very gracefully-arranged and attractive collection of fine plants. In the centre was a tall specimen of *Arundinaria Falconeri*, and around were grouped *Calanthe Veitchii*, *Cypripedium insigne*, single Chrysanthemums, *Crotoms* in variety, *Salvia leucantha*, *Panax Victoriae*, *Pandanus Veitchii*, *Dracenas*, *Eulalias*, *Dieffenbachias*, *Urcolina pendula*, *Eupatorium micranthum*, *Marguerite Boule de Neige*, *Aralia gracillimum* and *Colens*.

For a group of single Chrysanthemums, the first prize was won by Dr. Burke with a well-arranged group of plants laden with very fresh and well-coloured blossoms.

For a collection of salads in variety, a most pleasing table was contributed by Mrs. Bainbridge, who won the first prize. With its lightness of arrangement and the bright colouring of the Tomatoes and Capsicums it certainly provided one of the prettiest pictures in the show, and it would have been fully equal to winning in London in strong competition. Included in the collection of salads were five sorts of Capsicum, large red and yellow Tomatoes, Grape Tomatoes (yellow and red), American Cress, Australian Cress, Brazilian Cress, Watercress, Mustard, Batavian Endive, Moss-curl'd Endive, Cos and Cabbage Lettuce, Oak-leaved Lettuce, Asparagus-leaved Lettuce, Cucumbers, long and Turnip Radishes, Chinese Cabbage, variegated Chicory, red-leaved Chicory, Witloof, Chervil, Chibbles, Chives and Tarragon.

The nurserymen's exhibits were extremely fine, and contributed very noticeably to the attractions of the show. The Devon Rosery, Tarquay, which was awarded a gold medal, had a magnificent display of fruit, about one hundred and fifty varieties being shown, of which Apples accounted for nearly one hundred and twenty. The Apples were generally wonderfully well coloured and mostly very large in size. Of those more especially noteworthy some of the best were *Gascogne's Scarlet*, *Blenheim Orange* (very deep in colour), *Cox's Orange Pippin*, *Peasgood's Nonsuch*, *Newton Wonder* (excellent), *Bismarck*, *Bramley's Seedling* and *Emperor Alexander*.

The King's Acre Nurseries, Hereford, also carried off a gold medal for a very meritorious display of fruit. The outstanding feature of this stand consisted in several enormous specimens of the little-known Apple *Gloria Mundi*. Among the best fruit on the stand were *Lord Derby*, *Warner's King*, *King's Acre Bountiful* and *Mère du Méoage*.

Messrs. Sutton and Sons showed a first-class collection of vegetables, for which they received a gold medal. The produce was very well arranged and remarkably clean, of splendid quality and entirely free from coarseness. Every variety shown was perfection, and could not have been excelled.

Messrs. Robert Veitch and Son, Exeter, staged a comprehensive collection of plants, and were awarded a silver medal. In the stand were noticed hybrid *Nerines* and *Nerine Bowdenii*, *Cypripedium leucanum superbum*, *C. Acteaus*, *C. insigne punctatum*, *C. fairieanum*, *C. Charlesworthii*, *Odontoglossum crispum*, *O. andersonianum*, *Cattleya labriata*, *Sarracenia exoniensis*, *Zygopetalum Mackayi*, the new *Berberis Wilsonae*, *B. Bealii*, *Grevillea longifolia*, *G. ornithopoda* and a collection of winter-flowering Carnations.

MANCHESTER ROYAL HORTICULTURAL AND BOTANICAL SOCIETY.

THE autumn exhibition of this society was held in the Town Hall under the most favourable auspices. The entries, both competitive and non-competitive, were of a very high order, superior merit being the prevailing note in nearly every section.

Taking the Orchids, which were both numerous and choice, into first consideration, the season's best-known kinds were in evidence, such as *Cypripediums*, *Cattleyas*, *Vandas*, *Odon'toblossoms* and others, charming in diversity of colour, form and variety, and were greatly appreciated by the visitors. The gold medals that were awarded to the following firms were richly deserved: Messrs. J. Cypher, Charlesworth and Co. and W. R. Lee.

The Autumn Queen was in very high form. The exhibit of *Pantia Ralli*, Esq., in the premier class was of high excellence, and fully deserved the leading position. Among his blooms were fine types of *His Majesty*, *Glaucus*, *Superb*, *W. Mease*, *William Turner*, *Willie Rawlings*, *President Viger*, *Purity* and others in the Japanese section, with *Amber Beauty*, *Mrs. R. Judson*, *Boeace*, *G. F. Evans*, *Romance*, *Mrs. B. Haukey*, *Fred Palmer* and *Mrs. G.*

Denyer in the incurved section. Mr. C. Goves, gardener to Sir Gilbert Greenall, Bart.; Mr. C. Jones; Mr. W. E. Wright, gardener to Lord Sheffield; Mr. J. Stoney, gardener to Lieutenant-Colonel J. B. Gaskell; and Mr. W. J. Garner (nurseryman) also contributed many fine stands in this section.

Winter-flowering Begonias set up in large numbers by Messrs. Clibran proved one of the features of the show, with a bank of some thirty feet. The varieties were staged in groups, and perhaps the best of this set of good things were *Clibran's Pink*. Miss Clibran, Mrs. Heal and many others gave proof of what this firm have done by the introduction of these beautiful forms to brighten the winter months. Gold medal.

Fruit had a single representative in Messrs. Dickson, Brown and Tait, who staged a large collection of Apples and Pears of leading quality, well arranged. Gold medal. The secretarial duties and general management of the show were in the able hands of Mr. P. Weathers, and to him and his generous council a deep debt of gratitude is due.

EDINBURGH CHRYSANTHEMUM SHOW.

THE great annual show of Chrysanthemums organised by the Scottish Horticultural Association was held in the Waverley Market, Edinburgh, on November 14, 15 and 16. As might be expected from the increasing appreciation of small blooms in Scotland and their greater value for cutting, in addition to the unsatisfactory season, there was a smaller show than usual, and in the leading class the competition was more limited than ordinary. The cut flowers were, as a whole, of excellent quality; plants were good; and the floral arrangements in the best of taste, as a rule. Fruit was capital, and vegetables were of the usual high quality exhibited at this show.

Trade exhibits added a good deal to the interest and value of the exhibition. As usual, Messrs. W. Wells, Limited, Merstham, exhibited a magnificent display of new and old Chrysanthemums, which were greatly admired. Lady Talbot and Queen Mary were especially good, and the whole exhibit was worthy of the gold medal awarded. Messrs. Wells received awards of merit for Chrysanthemums *Queen Mary* and *Mrs. W. G. Braxall*.

From Messrs. Sutton and Sons, Reading, there came one of their superb exhibits, comprising the finest varieties of vegetables, &c., upwards of sixty varieties being shown in their wonted grand style. A gold medal was awarded to the firm.

Messrs. W. Cutbush and Sons, Highgate, London, received a silver medal for their excellent exhibit of Carnations, among which we noted *King George*, *Mrs. Lucy Mackinnon* and *Hon. R. James*.

The exhibit of Messrs. Young and Co., Hatherley, Cheltenham, who also received a silver medal, contained a number of the best and newest Carnations, among which we observed *Hon. J. Boscawen*, *Duchess of Devonshire*, *Empire Day* and many others of grand quality.

Messrs. Dobbie and Co., Edinburgh, made a fine exhibit, for which a silver medal was given. Their collection of Potatoes was one of great value and interest.

An exceedingly attractive display, though not large, was made by Mr. David W. Thomson, George Street, Edinburgh, who sent a collection of winter-flowering Begonias, which enabled growers to see some of the best of the newer varieties as grown in small pots.

Messrs. John Forbes, Hawick, Limited, set up an exhibit of good Carnations, Begonias, perennial Asters, &c.

The Professional and Civil Service Supply Association, Edinburgh, made an effective exhibit of Grapes, Apples and other fruits.

Mr. H. N. Ellison, West Bromwich, again sent one of his attractive exhibits of choice Ferns—a most interesting and pretty stand.

On the exhibit of Messrs. Fille, Whyte and Co., Edinburgh, there were many very fine vegetables, plants, &c., showing the excellence of the firm's strains.

In the competitive sections keen interest was displayed in the exhibits for the leading prizes. That for the City of Edinburgh Cup and £12 in money was, however, shorn of much of its attraction by the fact that of the three entries only for this season but two were staged, and the disparity between these was very great. Mr. T. Lunt, gardener to Captain Stirling of Keir, the hon. president of the association, was declared the winner, and thus becomes the owner of the cup, which he has now won for three times. He had 138½ points out of a possible 180. The blooms, though very fine, were not equal to those which won the cup in 1911. Out of the fifteen varieties *Mary Poulton*, Mrs. Thorn and William Turner were probably the finest; but good blooms of Mrs. A. T. Miller, F. S. Vallis, *White Queen*, *Purity*, *Maud Williamson* and others were included in this creditable exhibit. The second prize was withheld and a third awarded to Mr. J. Fraser, gardener to Mrs. Simpson, Bonaly Tower, for a nice exhibit, though too small for such a class. Mr. Fraser had 87 points.

A much closer competition occurred in the class for the Scottish Challenge Cup for Scottish growers, and Mr. James Small had a creditable win with a good exhibit which gained 76 points, the highest possible being 90. Mr. R. Mackenzie was only 1½ points behind. Mr. H. M'Skimming, who had 72½, was third; and Mr. D. McLean, Raith, had 71½ in the fourth-prize exhibit. As will be gathered from the number of points, this class also was hardly up to the usual.

For six vases, Japanese, confined to private gardeners and amateurs, Mr. John Waldie, Dollarbeg, was first.

For twelve blooms, Japanese, in twelve varieties, open to all, Mr. Lunt repeated his victory in the premier class. Mr. Small being second.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20 Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Tulip Show in London Next Year.—We understand that the Council of the Royal Horticultural Society will hold a special Tulip show in their hall at Vincent Square during the spring of next year. A considerable portion of the hall will be devoted to these flowers, and the suggested date of the exhibition is the Wednesday before the great spring show at Chelsea. We hope to be able to publish fuller details shortly.

The Grading and Packing of Fruit.—Since our last issue went to press, we have ascertained that the Federation boxes for packing fruit, mentioned by Mr. A. H. Pearson on page 586, can be obtained, cut ready for nailing, from Messrs. G. Monro and Co., Covent Garden; J. A. S. Smythe, Bridge Wharf, Maidstone; and W. and C. Pantin, 147, Upper Thames Street, London, E.C. The last named will not, however, supply less than 1,000 boxes.

The King's Spear.—In the King's Spear (*Asphodelus ramosus*) we have a capital plant for a moist and rather shady place, where this noble subject is seen in perfection. In dry, poor soil it does not increase well, and never shows its real beauty. If planted in good, rich, rather moist loam, it grows to 3 feet or more high, and gives above its long, narrow leaves branching spikes of white flowers. It is propagated by division or by seeds.

National Chrysanthemum Society's Shows for 1913.—The shows to be held by the National Chrysanthemum Society at the Crystal Palace in 1913 have now been definitely fixed for October 1 and 2 and November 5, 6 and 7, and the agreement has already been signed between the society and the authorities of the Crystal Palace. Will other Chrysanthemum societies throughout the kingdom kindly make a note of these dates with a view, as far as possible, to preventing any overlapping?

A Useful Climbing Groundsel.—In the Succulent House at Kew one of the showiest plants at the present time is *Senecio canalipes*, a South African species, which occupies a position on one of the rafters. Of succulent consistency, its long, slender branches attain a length of 15 feet or more, and are clothed with green, Ivy-like, fleshy leaves on stalks 2 inches to 3 inches long. At the present time it is covered with large heads of bright yellow flowers, which appear from the points of the branches. In some instances these inflorescences are as much as 9 inches across, while the individual heads are nearly an inch in diameter, the ray florets being more conspicuous than the disc florets. It is well adapted for planting in a structure where a minimum winter temperature of 40° to 45° is maintained, and is suitable either for a rafter, pillar or trellis.

Chrysanthemum Mrs. Gilbert Drabble.—Our Paris contemporary *La Vie à la Campagne* gives as its cover illustration for its issue of the 1st inst. a gigantic picture of Mrs. Gilbert Drabble, from a photograph of the bloom staged last year at the Paris Show by Mr. Thomas Stevenson, and which was awarded the silver-gilt medal for the finest bloom in the show. There are in the same issue several other reproductions of Chrysanthemums grown by this eminent exhibitor.

The Himalayan Rockspray.—*Cotoneaster frigida*, native of the Himalaya, is a most attractive winter shrub by reason of its bright orange crimson fruits. If untouched by birds, these fruits remain showy throughout the winter, and there are few shrubs that can vie for effect with the well-berried and half-drooping branches of *Cotoneaster frigida*. At this season the berry-crowded branches are particularly fine, making this shrub very useful for grouping in places where late autumn and winter effects are desired.

The Constantinople Nut.—This interesting Hazel, known botanically as *Corylus Colurna*, is producing Nuts with remarkable freedom this year. The Nuts are produced in clusters of usually five or six, and are somewhat smaller than those of the common Wood Nut. There is also a good promise of male catkins for the coming spring, and the young catkins and clusters of Nuts make this tree interesting at this season and at this eventful period in the history of Constantinople. The tree will attain a height of 60 feet, and was introduced from Asia Minor in 1665.

A Beautiful Berried Shrub.—One of the most ornamental shrubs in the garden just now is *Cotoneaster Simonsii*, a fairly common, semi-evergreen species from the Himalaya. Its almost erect, slender branches are thickly clothed with oval-shaped, orange scarlet berries that were highly iridescent in the wonderful sunshine that was experienced in many districts last Sunday. This *Cotoneaster* will thrive in almost any kind of soil, and we have seen it successfully used for a hedge where strict formality of outline was not desired.

The Pyrenean Adonis.—*Adonis pyrenaica* is one of the useful hardy flowers which have never been appraised at their real value. It is not nearly so plentiful in gardens as the Spring Adonis (*A. vernalis*), though it has several good qualities to commend it. It comes into bloom later than its ally of the spring, and is rather taller, growing to 1 foot or 15 inches high. From the root it sends up stems bearing narrow leaves and good-sized yellow flowers, which appear about May. It will thrive in any good loamy soil, and is always finer in one inclining to stiffness than in a light and open one.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

November Rose Blooms.—In a recent issue there appeared a note about the gathering of some good Roses in an Essex garden on November 3. On November 11 in this garden—Ken View, Highgate—twenty four really good flowers of the following varieties were gathered: Richmond, Mme. Abel Chatenay, Dr. C. Hall, D. Page-Roberts, La Tosca, Lady Ursula, Conrad Meyer, Comtesse I. Hardegg and Mme. E. Metz. Such a rich find must have been impossible had it not been for the spell of mild weather we have experienced.—T. C.

Lilium longiflorum.—I was much interested in one of the "Notes of the Week," issue November 16, on the Lilium above named. It is, indeed, an ever-welcome flower, useful for cutting, especially for placing in the tall, trumpet-shaped vases now so fashionable for the furnishing of the greenhouse and the conservatory. Amateur cultivators are very fond of this Lilium, and I would like to refer to the fact that the plants are often sadly crippled when subjected to a cold temperature suddenly after being forced on in a warm house and moist atmosphere in the early stages of growth. Having seen so many fine plants ruined in this way, I would like to warn the beginner against causing such sudden checks to the growing plants.—G. G.

Daffodils in New Zealand.—I have just received from a Colonial customer copies of the New Zealand *Weekly Graphic* dated September 18 and 25, giving an excellent account and particularly good illustrations of the Auckland Daffodil Show held on September 5 last. Judging from the account of the show and the capital photographs reproduced of individual blooms, this go-ahead Colony bids fair to become a formidable competitor of the Old Country. The raising of seedlings, too, appears to be making some headway, and among flowers exhibited at the show may be numbered Trewithiel, Prime Minister, Trafalgar, Aorangi, Tongariro and General Manager. All these flowers were raised by Professor Thomas, and, to judge by the large bunches of Trewithiel and Tongariro, he has evidently been working with the Daffodil for some years. I may add that interesting pictures also appear in one of the papers of groups taken at the National Sweet Pea Society's trials at Sutton and Hinckley, everything being reproduced in excellent form and little trouble being experienced in picking out leading lights of the English Sweet Pea world.—F. HERBERT CHAPMAN.

Charming November Flowers.—Quite near a path in the alpine or rock garden the lovely dwarf-growing *Polygala Chamæbuxus purpurea* and *P. C. grandiflora* are just now in full flower, and are very beautiful for the dull month of November. The first named soon grows from a small plant into a good mass, and may be made use of in many parts of the garden, as a carpeting, for instance, to Azaleas and Rhododendrons. It being an evergreen, it is of more interest among deciduous Rhododendrons. *P. C. grandiflora* is also quite hardy, and the flowers are creamy white and most freely produced. Each resembles a small Sweet Pea. Neither of these grows more than about nine inches high, so that they are good plants for small as well as large gardens. They are also very easily propagated by layers or cuttings, and soon make nice sized clumps. They will grow in nearly any soil in which a little fine peat and leaf

soil has been incorporated. The drainage should be made good and the plants confined to the shady side of the border or alpine garden, or wherever they are planted, as they love shade (not overhead) and moisture. In February and March, when blooming is over, it is well to protect the growths from cutting winds by placing a little peat or leaf-soil or Bracken around them, when the plants will stand many degrees of cold without the least injury.—W. A. COOK, *Leonardslee*.

The Grading and Packing of Fruit.—This subject, referred to on page 586, issue November 23, by Mr. A. H. Pearson, with an editorial footnote, is a very important one. For ten years I marketed fruit, from Grapes to Strawberries, and during that time only lost 6s. owing to faulty packing out of many hundreds of pounds' worth of produce. Through grading and packing mainly in boxes with tissue paper, cotton-wool and dried beaten moss raked up in the fields, we secured the highest prices. Moss, where filling-up material is necessary, well beaten and prepared, does not taint fruits, and this I proved by packing annually about four thousand Peaches and Nectarines in it. In addition to grading carefully, we advised the salesman the night previous to the despatch of the goods what to expect, and as he could rely upon the quality, the produce was often sold the next morning before it arrived at its destination, and higher prices were secured. With regard to Pear Marie Louise flowering too easily on warm walls as to be generally destroyed by spring frosts, mine were given just sufficient light protection to prevent such loss, and, having trees in other positions, the supply of these fruits was prolonged a little. I quite agree with Mr. Pearson that Victoria Plum does best grown in the open, and have not found examples more satisfactory than those grown as bushes.—B.

Rock Gardens in the Making.—Mr. E. H. Jenkins, the writer of the article on the above subject, page 590, strikes the true note in all he says about the natural grouping of the rock necessary in the making of a good rock garden. I am glad that he gives unstinted praise to a certain rock garden at the last International Show. This, to my mind, stood out *facile princeps* above all the rest, its effectiveness resulting from its simplicity and from its truth to Nature in her happiest and most reposeful mood. Mr. Jenkins says truly that "far too many artificial rock gardens err on the side of pretentiousness." Many builders of rock gardens seem too desirous of showing off their rocks rather than the exquisite inlaid jewellery of an alpine slope. They err in piling up their blocks of sandstone or limestone as though they were the "tumbled fragments of an infant world," and I find it is no easy matter to persuade people to have their fine rocks deeply embedded, or, indeed, bedded at all, in the loamy banks prepared for them. It is quite a mistake, however, to have the rocks too prominent. One of the best examples to follow is some natural outcrop of rock, not too clearly defined nor too regular, as in the level rocky terraces in the cañons of the Colorado, but where former lateral and vertical pressure has altered the stratification, and where the tops of the rocks have been discovered by the processes of denudation, and where weathering has played its part in the ages. This is well exemplified by Mr. Jenkins when he writes about the "teachings of our own hillsides," and I am looking forward with great interest to more articles of his on "Rock Gardens in the Making."—G. H. ADDY, *Ightham, Kent*.

Fragrance in Chrysanthemums.—In a "Note of the Week" (October 26), on the single Chrysanthemum Eric Harvey I was particularly impressed by your words "It is very fragrant." Now, was not your comment somewhat remarkable? I suggest it was for the following reason. Looking up four well-known garden books—one of them being on Chrysanthemums only by an expert—also various notes and articles by writers in papers on this flower, I find no reference whatever to any indication of fragrance. Why is this? Perhaps some authority on this favourite will offer a few remarks. Fragrance is such a recommendatory virtue for a plant to possess that surely there can be nothing but added interest and extended admiration in store for the Chrysanthemum should it be found to be the owner of such sweet wealth. A short time ago I had some sprays of a pink Pompon given me, and it was the decided sweet smell of these which made me take note of your remark; the variety was given as Hannah Stacey. Since then I have had some pieces of a single pink, with a slight inclination to streaks of white on some of the petals, also given me, and this was still more perfumed. Its name I do not know. Is the fragrance only to be found in certain singles and Pompons? Come forward ye 'Mum authorities and explain. The usual eulogies of this flower are: Last long when cut; useful for decoration; lovely and numerous colours, &c. Can the books and catalogues of the future hope to add the further commendation? Some are fragrant.—C. TURNER. [The flowers of the variety Eric Harvey emitted a delightful fragrance that reminded us of honeycomb. Unfortunately, this is not found in many other varieties, but we should be glad to hear of others that are fragrant.—Ed.]

How to Exterminate Moles.—In a recent issue of THE GARDEN a correspondent was advised that nothing could be done to destroy moles under trees, and was advised trapping as a remedy; but to catch a mole in loose soil with the ordinary iron trap is, to any but an expert, a most difficult feat, and few seem to know the habits of the creature well enough to select the right part of the run in which to place the trap. It is not generally known that moles are easily caught in pitfalls placed in the main runs. Deep, narrow biscuit tins or earthenware jars, such as are commonly used in gardens to trap mice, may be used. The receptacle used must be sunk till the top is exactly on a level with the bottom of the run, which must be carefully smoothed off and end abruptly at the edge of the jar or tin, and be covered with a slate or tile to exclude all light. But by far the easiest way of destroying moles and all other underground vermin is by injecting bisulphide of carbon in their runs and burrows. Open the run near where the moles are working or where they have their nests and pour in an ounce of the bisulphide, and at once cover tightly with a flat stone or tile to prevent the fumes from escaping. Leave it thus for a couple of minutes, then remove the covering and apply a lighted match to the hole and explode the vapour, when any vermin within reach of the fumes will be instantly killed. The liquid should not come into actual contact with the roots of any plants or trees, but the vapour will do them no harm. It must be remembered that bisulphide of carbon is both poisonous and very highly inflammable. It must on no account be brought near fire, and the person using it should not be smoking at the time. It is, however, a most useful substance, and by its aid the garden can be kept free of many underground pests.—H. C. WOOD, *The Gardens, New Place, Lingfield, Surrey*.

A Hybrid Chestnut.—At this season many intending planters are, naturally, on the look-out for rare and little-known subjects for the garden and pleasure grounds. *Æsculus plantiërensis* is a distinct and pleasing hybrid Horse Chestnut raised in the nursery of Messrs. Simon Louis Frères at Plantières-lès-Metz. It came from a seed of the common Horse Chestnut, which had been crossed, presumably, with *Æ. carnea* (rubicunda). In habit and growth the young trees are as free as the female parent. The flowers are delicate pink or pale rose in colour, the size of the terminal racemes being about the same as those of the common Horse Chestnut. An important point in favour of this tree for planting in public parks, open spaces and streets is that it does not produce fruits. Those in charge of the places named, where in the past the common Horse Chestnut has been freely planted, know only too well the trouble and often danger entailed in autumn by boys throwing sticks and stones up into the trees as long as there are fruits hanging.

Iris gracilipes.—One of the daintiest of all the lovely species of the Fleur-de-Lis which ever graced a garden is *Iris gracilipes*, a gem of the first water without cavil, and a rare beauty which should find its way into every rock garden or choice border where the very *élite* of plants are to be found. It comes from Northern Japan, and belongs to the Evansæ section, one which includes the lovely *I. tectorum* also, with *I. cristata*, *I. lacustris* and a few more. Words fail one in attempting to tell of it. It is less than a foot high with me, the leaves attaining about that length when fully developed and the stem being somewhat below that stature and carrying delightful little lilac flowers with a yellow crest down the falls. Such is a bald description of the main colouring, but it is insufficient to convey a full idea of the shading and marking of this delightful *I. gracilipes*. It flowers in summer with me, and is thriving in the rock garden on a flat spot in loam, sand and grit. It is a rhizomatous and not a bulbous *Iris*.—S. ARNOTT.

FORTHCOMING EVENTS.

December 2.—National Chrysanthemum Society's Floral Committee Meeting at Essex Hall, 3 p.m.

December 3.—Royal Horticultural Society's Meeting and Perpetual Flowering Carnation Society's Show (two days). Lecture on the first day by Mme. de Tzikos St. Leger on "The Vegetation of the Island of St. Leger in Lago Maggiore." Scottish Horticultural Association's Meeting.

December 5.—Linnean Society's Meeting.

December 7.—Société Française d'Horticulture de Londres Meeting.

December 9.—United Horticultural Benefit and Provident Society's Committee Meeting.

December 11.—North of England Horticultural Society's Meeting at Leeds.

GARDENS OF TO-DAY.

WESTWICK GARDENS, NORWICH.

THROUGHOUT the broad acres of Norfolk the craft of gardening occupies a prominent position in the eyes and minds of the public. The East Anglian Horticultural Club, with its head-quarters at the ancient city of Norwich, is one of, if not the strongest in the country, and among the most highly respected of its members is Mr. G. Davison, head-gardener at Westwick, the beautiful and old-world seat of Colonel Petre. The grounds at Westwick comprise

completely revolutionised the flower and given us varieties beyond the wildest dreams of imagination. It is now nineteen years since he first set himself the task of improving this flower, and by working on well-defined lines he has this year startled the whole world by giving us that beautiful variety *Star of the East*, which has already gained three first-class certificates, including one from the Royal Horticultural Society. Five years ago Mr. Davison secured the first seedling of this magnificent flower, and now he has about one thousand seven hundred plants, one of the accompanying illustrations showing a border in the kitchen garden filled with it. We hope next spring to publish a coloured plate of this *Montbretia*, which has flowers of rich orange red colour and from 4 inches to 4½ inches in diameter. When Mr. Davison first started working among the *Montbretias*, he had the variety *crocosmæflora*, and a variety named and raised in France, *Golden Sheaf*. These he crossed, and since that time all the beautiful varieties he has given us have been secured by intercrossing his own seedlings. Among these earlier varieties are *George Davison*, *Ernest Davison*, *King Edmund*, *Hereward*, *Westwick*, *Norwic* and *Prometheus*. All these secured awards of merit from the Royal Horticultural Society, and, in addition, *Prometheus*, sent out six years ago, and of which a coloured plate was published with our issue dated January 19, 1907, was awarded first-class certificates at the following shows: Shrewsbury, York, Edinburgh, Amsterdam and Paris. Now it is eclipsed by *Star of the East*. Mr. Davison's method of growing *Montbretias* is as follows: Plant in March in good, sandy loam that contains a fair quantity of leaf-soil, select a rather cool position, and give the plants plenty of moisture. Lift in autumn and store in a cold frame with their tops shortened to about six inches, just keeping severe frost away. Take the lights off on fine days.

A WELL-TRAINED TREE OF PEAR DOYENNE DU COMICE AT WESTWICK GARDENS.

about two thousand acres, the greater part of which is devoted to woodland and a large portion to a fruit farm, all of which come under the supervision of Mr. Davison. In the woods is one of the most beautiful pieces of ornamental water that we have seen outside the borders of Scotland, its banks being planted with Scotch and Cluster Pines that impart a sense of grandeur to the whole. But it is of the gardens that we would specially write.

The Montbretias.—When, in the future, some scribe essays to write the history of these beautiful hardy flowers of late summer and autumn, it will be necessary for him to devote several chapters to Mr. Davison's work, for he has

The Flame Flower.—This beautiful plant, *Tropæolum speciosum*, the despair of so many gardeners, is grown remarkably well at Westwick. Mr. Davison gives it a north or north-west position against a wall some twenty feet high, draping old fish-netting for it to climb over. In his opinion it needs a very cool root-run, with plenty of humus and sand in the soil. Every other year in February he lifts the roots, digs out the old soil to a depth of 18 inches, fills in with good soil, and replants the roots about four inches deep. These plants grow about twelve feet high the first year, and the next season reach the top of the 20-foot wall and flower profusely. By treating a portion in this way each year, growths of one and two years are always available.

Gentiana acaulis Eighty Years Old.—A particularly interesting feature at Westwick is two oblong beds of this charming alpine, which have

been in existence at least eighty years and possibly well over a century, and which have never been disturbed. The plants are remarkably healthy, and at the time of our visit in mid-September had a few of their rich blue flowers standing well up above the carpet of green foliage. Mr. Davison's family have been gardeners at Westwick for about a century, his father, grandfather and great-grandfather occupying that position before him, and it is through this long family association with the gardens that the age of the Gentsians is known.

The Herbaceous Border.—This is one of the features of Westwick, and one that owes its inception to Mr. Davison. During the whole of spring, summer and autumn it is exceptionally beautiful, and, in common with everything else that he sets his hand to, the flowers are all particularly well grown. Those who visited the horticultural section of the Royal Agricultural Society's show at Norwich last year will no doubt remember the magnificent exhibit of hardy flowers staged by him there. The accompanying plan of this well-designed border will, we hope, prove useful to others at this season of planting.

The Pergola.—Running from the mansion to the kitchen garden is a beautifully-designed pergola about one hundred yards long, thirteen feet wide, twelve feet high. This was erected by Mr. Davison about seventeen years ago, the pillars being bold Larch trunks. These have just had to be replaced, and he has now selected Chestnut, which, he thinks, will be more durable. The wrought-iron gate, which admits the visitor from the pergola to the kitchen garden, is one of the finest examples we have ever seen, and is of local workmanship, being made at Norwich.

Daffodils and Habranthus.—To show the activity of this excellent gardener, we must just mention that the hybridisation of Daffodils has received his attention for some years past, and several high-priced varieties that have been placed on the market during recent years by the leading firms have been raised by him. Habranthus pratensis, too, he grows in abundance, planting the bulbs outside much in the same way as he does his choice Daffodils. We should say that Mr. Davison has the largest stock in the world of this beautiful and rather rare bulbous plant.

Pears.—All hardy fruit is particularly well done at Westwick, but of Pears Mr. Davison makes a

MR. G. DAVISON, THE RAISER OF THE NEW MONTBRETIA PROMETHEUS AND STAR OF THE EAST.

speciality. Go where you will, you find Pears growing to perfection, the walls being covered with beautifully-trained trees. At the British Fruit Show held by the Royal Horticultural Society in London, Pears grown at Westwick have won many prizes, beating those grown in the more favoured county of Kent; and for the benefit of any who may be sceptical on the point

we may mention that Mr. Davison has not a single tree growing under glass. Doyenné du Comice is his favourite variety, and it is interesting to note that in the spring, when the flowers are open, artificial pollination, with the aid of a rabbit's tail fastened to a long stick, is resorted to. The whole of the trees are beautifully trained and well cared for, the accompanying illustration of a specimen of Doyenné du Comice giving some idea of the method adopted.

A New Black Currant.—With the idea of securing a new late-ripening Black Currant with a tough skin, so that it will travel well, Mr. Davison has commenced crossing existing varieties, and already he has some eight thousand seedlings well on the way. That he will be as successful as he has been in other directions we have little doubt.

STERILISING SOIL FOR EELWORM.

A CORRESPONDENT asks for directions as to sterilising earth for the destruction of stem eelworm. It is difficult to answer such an indefinite question, for everything depends upon the quantity of earth to be dealt with and where it is. Partial sterilisation of the soil is an efficient means of dealing with several pests that live in the soil, eelworms in particular, and it has the further curious effect of first delaying growth for a very short time, then hastening it, so that plants put into such soil quickly overtake those put into similar but untreated soil. The cause of this appears to be as follows: Most of the bacteria are killed, but not all. The minute animals that prey upon the bacteria are also killed, as well as eel-

worms and so on. The bacteria that remain are able to grow at a rate far exceeding that of those in soil where their animal enemies abound, and in growing they produce from the decaying matter which forms their food a correspondingly greater amount of ammonia. Plants, therefore, in this partially sterilised soil have greater stores of ammonia at their disposal than those in untreated soil and are consequently able to grow more rapidly. Other advantages are the prevention

A BORDER OF THE NEW MONTBRETIA STAR OF THE EAST IN THE GARDENS AT WESTWICK, NORWICH.

of the growth of moss on seed-pans and the destruction of weed seeds.

By far the most efficient method of effecting partial sterilisation is by heat. Other methods not so efficient, but able to be applied under certain circumstances, are flooding, drying out and the use of chemicals.

Heating by Steam.—The most effective way of heating is by the application of steam. Dry heat apparently occasionally causes undesirable changes, which check growth to a very great extent; but probably this is most marked when a high temperature is reached. As a rule, if a soil mass can be heated to 180° Fabr., that is sufficient to ensure most of the benefits of partial sterilisation. It is obvious that heat such as is required cannot be applied on a large scale outdoors, but on a small

but this should not be done to such an extent that the soil becomes charred. Several methods besides the use of the kitchen oven are in vogue. Heating the soil on a shovel over a fire, thrusting red-hot iron plates or even hot bricks into the soil heap, may be practised.

Treatment by Chemicals.—Carbolic acid, formalin, naphthalene, carbon bisulphide and so on are used at times; but their use is not unattended by danger to the crops to follow, and is not always satisfactory. The only method which at present seems to offer some degree of success outside is the use of powdered quicklime, dug in while still in a thoroughly caustic state. Potash salts also apparently have a slightly sterilising effect, especially kainit. No doubt in time some substance injurious to animals, such as the eelworms

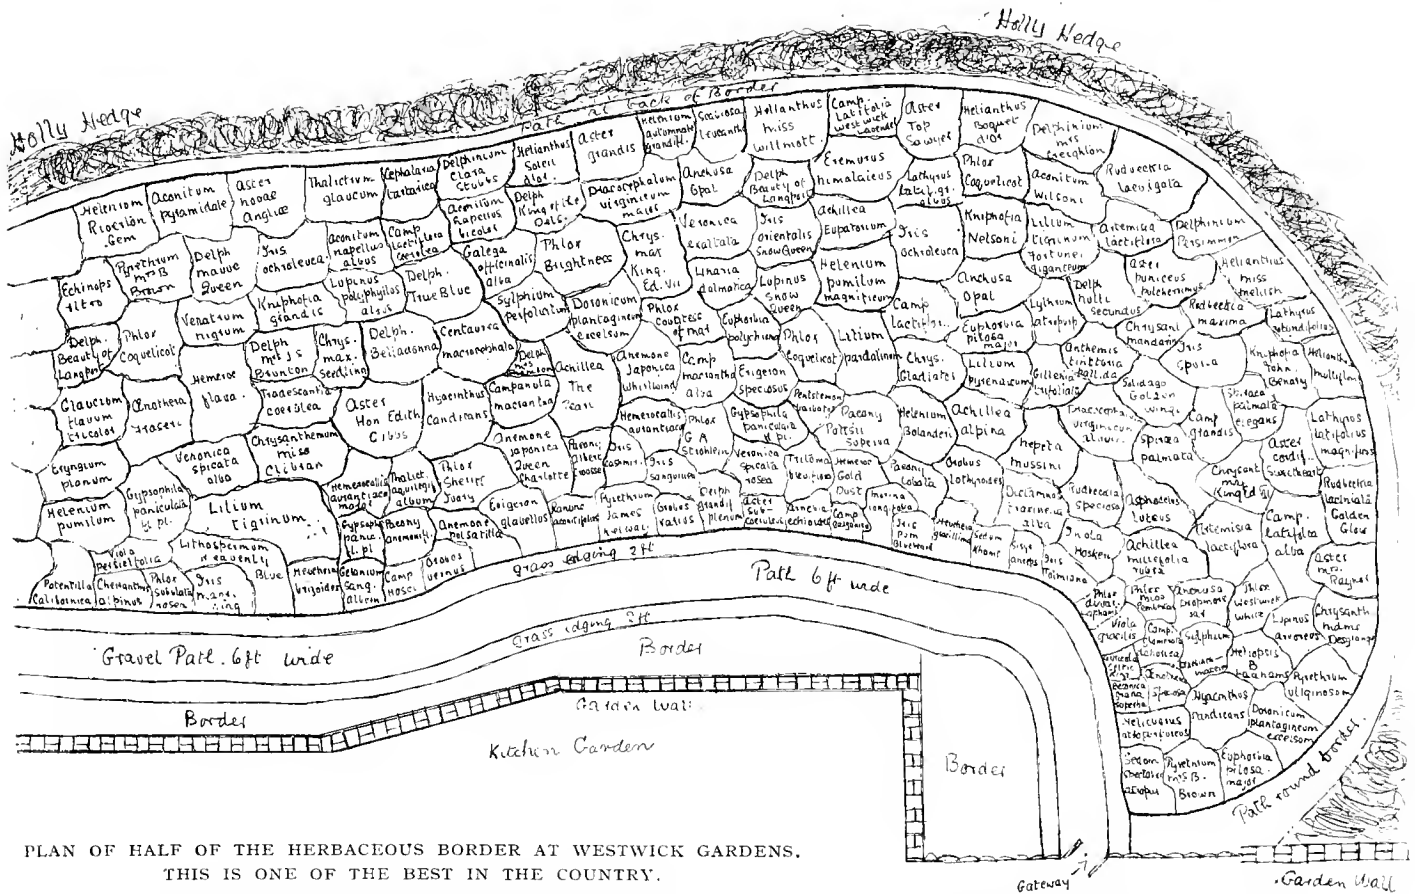

THE ROSE GARDEN.

NOTES ON NEWER ROSES. HYBRID TEAS FOR EXHIBITION.

(Continued from page 589.)

Mrs. George Sawyer (Lowe and Sawyer, 1911).—As seen exhibited by Messrs. Mount and others, this Rose promises well from the exhibition standpoint; but I have not grown it myself, although I hope to do so next year. It is a nice pointed flower, with petals of good substance, and its growth, I am told, is excellent. Another flesh-coloured flower, but with rather more contrast than most Roses of this colour have got.

Mrs. J. H. Welch (S. McGredy and Son, 1911).—This Rose obtained the gold medal of the National

PLAN OF HALF OF THE HERBACEOUS BORDER AT WESTWICK GARDENS. THIS IS ONE OF THE BEST IN THE COUNTRY.

scale it may be easily managed. Taking steam first, we may have a box or tank made with pipes perforated at intervals running along the bottom, and after putting the soil to be treated into it and covering over with a canvas cloth, we may drive steam from a boiler through it. If this method be adopted (as is done in several commercial growers' places now), pressure of 60lb. to 80lb. to the square inch is required. A modification of this method is in use in greenhouses, where a movable frame of perforated pipes is laid so as to cover half a bed, and soil from the other half is thrown over it and covered with canvas. The steam is then driven through and the temperature raised to the required degree. The frame can then be moved on, and so the whole house may be treated a piece at a time.

Baking the Soil.—Where steam-heat cannot be obtained, baking the soil may be resorted to;

and minute creatures which prey on bacteria, will be found sufficiently cheap to act as a soil steriliser, and with it will begin a new era for those whose business it is to gather the riches of the soil.

SCIENTIST.

BUDDLEIA OFFICINALIS.

Those who are responsible for keeping a greenhouse or conservatory furnished during the winter and spring months will find a batch of this Chinese Buddleia of great service, for it has a prolonged flowering period. It can be grown as a small bush in a 5-inch or 6-inch pot, and such a plant may be expected to bear up to a dozen inflorescences. The lilac-coloured flowers are borne in dense, terminal panicles from early December until February, and during the greater part of the time the plants are in first-rate condition. The lance-shaped leaves are greyish in colour.

W.

Rose Society at the same time and place as Edward Mawley, and perhaps has been somewhat overlooked in consequence. Of the two it has been far more reliable with me. It is an enormous flower—I think probably the largest Rose we have; but, at the same time, it has very few petals. I know of no Rose more deceptive in appearance in this respect, but it retains its shape in a marvellous fashion for several days, and then falls wide open into a flower as large as a small cheese plate. It is a Rose that I can strongly recommend, notwithstanding these characteristics. Its growth is vigorous; it produces its flowers freely and continuously (they must be disbudded), and they are held erect. At its best it is a most brilliant colour, very distinct, which one can only describe as a rose pink, but at times extraordinarily rich and brilliant, and quite unlike any other pink that I can call to mind. It has a slight perfume.

Mrs. Maynard Sinton (S. McGredy and Son, 1910).—Another Portadown Rose of merit. Its colour is pale flesh, almost white; flowers of large size, apt to come perhaps too big for elegance, with a very delicious perfume. Those grumblers who are always saying that Roses are losing their fragrance are not up to date, as many of the new Roses are the most fragrant that we have, and this is an excellent example. It is not a vigorous Rose, but a very healthy, robust grower, with good, sturdy shoots well able to support the large flowers that are produced at the end of each shoot. Very nearly mildew-proof. It was awarded the gold medal at Salisbury Show in 1909.

Mrs. Muir Mackean (S. McGredy and Son, 1912).—This Rose has been one of the successes of the year in my garden, and I can very strongly recommend it to exhibitors and, in fact, all Rose-lovers. Its flowers always come good and are most freely produced. At the time of writing (the second week in November) my plants are covered with buds. Its habit of growth is all that is desirable, and not too vigorous, as most of the red Hybrid Teas are apt to be. It is a self-coloured flower of deep carmine-crimson of quite perfect shape. When I have added that it is fragrant and practically mildew-proof, it will be seen that there is very little fault to be found with this latest production from these raisers. It can be best described as a darker and improved Mrs. A. E. Coxhead. It is distinctly a reliable Rose, in the sense that its flowers are always of good shape and up to exhibition standard. Its colour stands well in any weather, and in my opinion it is one of the best Roses of the year. It received a silver-gilt medal at Ulverston and a card of commendation at the autumn show in 1910; but many a Rose not half as good as this one has had the gold medal.

Mrs. Sam Ross (Hugh Dickson, 1912).—Another Belmont variety that I am inclined to think is the best Rose of a very strong set of four that this firm are sending out this year. There is a refinement about this Rose that must appeal to everyone. I fell in love with it at first sight at the Royal Botanic Show in 1911, and my first impressions were confirmed at Belmont, where some glorious rows of it were in full flower. The Roses had had two or three days' rest, so good flowers were numerous. It is a pale yellow, the colour shading from straw colour to almost a chamois tint; but this is a very inadequate description. The flowers are of large size, with plenty of good-shaped petals that in the open flower are reflexed at the edges. The growth is upright, and the flowers are held erect and sweetly perfumed. A Rose that will be a great favourite with the ladies. A gold medal Rose that the raisers think very highly of, and rightly so, too.

Southampton HERBERT E. MOLYNEUX.

(To be continued.)

TREES AND SHRUBS.

THE BEST TREES AND SHRUBS FOR SMOKY TOWNS.

THOSE who are expected to keep gardens gay in smoky towns are severely handicapped, for they are prevented from planting many of our most ornamental plants, and even those subjects which give the most satisfactory results rarely attain the degree of excellence which we are apt to associate with them when growing under other and better conditions. Smoke is not always the worst enemy either, for in addition to smoke there are fumes from chemical and other works which render most phases of gardening impossible,

sparingly, for they have less chance of success than deciduous shrubs; the latter shed a considerable amount of dirt with their leaves in autumn. The leaves of evergreens, on the other hand, get dirtier as the winter progresses, and the pores become so choked with dirt that they cannot fulfil their proper functions. Those evergreens which are selected should be kinds with glossy rather than dull leaves, as dirt is more easily removed by rain from the former than from the latter. Evergreen conifers ought not to be planted in or near a smoky town, for they never thrive in an impure atmosphere.

The common Holly (*Ilex Aquifolium*), together with its glossy-leaved forms, is one of the best evergreens for smoky towns, and fairly good examples may be noted about the metropolis. For instance, a number of good bushes are to be seen in Camberwell Park, which is in a very thickly-populated neighbourhood, and the atmosphere is heavily charged with smoke. Then the Aucuba gives good results in many places. The common Ivy thrives under the most unsatisfactory conditions, while its numerous tree forms also give satisfaction. *Berberis stenophylla* thrives fairly well, but, with many other shrubs, it ought not to be allowed to stand too long, and as soon as signs of deterioration are noticed it should be replaced by a healthy young plant. *B. Aquifolium* and the common Box are other evergreen shrubs which may be planted.

Among deciduous trees and shrubs, several instances of different kinds flourishing under unsatisfactory conditions may be noted in the City of London. Almost within a stone's throw of the Bank one or two well-developed Mulberry trees are to be found. A specially fine one is to be seen in a small garden attached to the offices and rooms of the Honourable Company of Girdlers in Basinghall Street. This must be at least 30 feet or 35 feet high, with a considerable spread, and a good crop of fruit is ripened each year. *Catalpa bignonioides* is another tree which gives good results in the heart of London, while the Plane has become famous the world over by reason of its happy knack of resisting the enervating effects of the London atmosphere. The Horse Chestnut

THE SNOWY MESPILUS (*AMELANCHIER CANADENSIS*), EFFECTIVELY PLANTED WITH A BACKGROUND OF DARK EVERGREEN TREES.

(See page 603.)

and sorely try the skill and patience of the cultivator. As evidences of the worst conditions, reference may be made to such towns as Runcorn and Widnes, on opposite banks of the river Mersey, and to Sheffield and Rotherham. The latter town has been very hardly hit during the last ten years, for the opening of numerous large coke ovens, with their attendant fumes, has made tree-life almost impossible. Still, by perseverance some things can be found which will thrive, or at any rate live, under even these conditions; while when smoke only is the drawback, a considerable number give moderately good results.

When selecting trees and shrubs for smoky towns, those with evergreen leaves should be chosen

is not a good tree for resisting smoke, and in the smokiest parts of Glasgow it is seen as a miserable example with poorly-developed leaves. The same remarks apply to the tree in Rotherham; but, curiously, the red-flowered Horse Chestnut grows as well as any tree can be expected to under such unsatisfactory atmospheric conditions. This is apparently a case of a hybrid tree being more vigorous and having a better constitution than its parents.

The Ash resists smoke fairly well, but the Beech does not. *Robinia Pseudacacia* is another tree to plant in smoky towns, while *Ulmus glabra* does moderately well. *Pyrus pinnatifida*, *P. rotundifolia* and others of the *Aria* group are good trees

for smoky towns, as may be seen in the smokiest parts of Glasgow. Mr. Whitton, the very able Parks Superintendent of that city, appears to have been one of the first to discover the smoke-resisting capabilities of *P. pinnatifida*, and he uses it largely.

The various kinds of ornamental Crabs may all be used, *Pyrus floribunda*, *P. spectabilis* and *P. Ringo* being a good trio. Flowering Thorns also do fairly well. The common Lime is never very satisfactory in a smoke-laden atmosphere. At the best of times its leaves begin to fall early, and when the atmosphere is bad, many leaves fall during the first half of August. As a rule, trees which start into growth late have a greater chance of success than those which commence growth earlier in the year, while both trees and shrubs with glabrous or almost glabrous leaves usually thrive more satisfactorily than those whose leaves and branches are hairy.

Of deciduous shrubs, the Flowering Currants, Philadelphuses, Lilacs, *Viburnum Opulus* and its sterile variety, species of *Cytisus* and *Genista*, *Forsythias*, *Diervillas*, *Prunuses*, *Cotoneaster frigida*, *Deutzia crenata*, *Rhus typhina*, *Cornus alba Spæthii* and *variegata*, and *Lonicera tatarica* may be planted; but provision must be made for replanting occasionally, for, once they begin to show signs of weakening health, there is little chance of their recovery, no matter what method of culture is tried; therefore it is better to start again with vigorous young stock. All that can be done by working the ground thoroughly and providing good soil to help to establish the plants should be carried out, for a good start is more than half the battle. It is also a good plan to hose the shrubs and small trees overhead occasionally, in order to remove as much dirt as possible before it can become firmly fixed on the leaves and branches. W. D.

THE SNOWY MESPILUS.

(AMELANCHIER CANADENSIS.)

Few hardy shrubs are so well named as the Snowy Mespilus, which in late March or in the early days of April is so smothered with the profusion of its pure white flowers as to resemble a huge snowdrift in the distant effect. Flowering as it does so early in the year, it is advisable when planting to choose a position where its flowers will show to the best advantage, such as a background of the Evergreen Oak or Holly would provide. When planted in association with early-flowering shrubs, such as Almonds and double Cherries, the bright effects so produced are pleasing in the extreme.

The Snowy Mespilus belongs to the large Natural Order Rosaceæ, and has for its near relative the common Medlar (*Mespilus germanica*), but the flowers of *Amelanchier* are much smaller; indeed, it may be regarded as one of the daintiest and most profusely-flowered trees in cultivation. It is not in the least particular in regard to soil, and, in common with the Bird Cherry and Thorns, it revels in sandy woods. There can be no doubt at its hardiness, as it succeeds in all parts of the British Isles.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Continued from page 590.)

Overhanging Rocks.—In rock garden building there is perhaps no greater error than that of the overhanging rock, and the more so when arranged according to the mason's plan as opposed to that of the intelligent gardener. In the case of the first named, the rocks are usually cemented together in more or less stereotyped fashion, and at such times the error resolves itself into a source of danger, and for the following reasons: Cemented joints, according to the mason, ensure stability. I agree. They also ensure that the crevices between the rocks contain no soil; hence the impossibility of garnishing them with plant-life. I repeat again, and the fact should be kept well in mind, that every rock garden should be a home—a happy one, too—for alpine plants, and not what it might prove to be—the most fiendish of cemeteries

garden is the variety of aspects that a thoughtful arrangement of the rocks affords. For example, a miniature ravine in a cool and sheltered or, preferably, moist place would be ideal for colonising *Haberlea* or *Ramondia*, while these same plants would be perfectly happy in nearly vertical crevices where an amply-supplied larder was within their reach, and where in dry weather a perforated pipe at will emitted its refreshing draught. For such things north or north-western aspects are excellent, while for similar positions on the exposed sun-kissed sides there are hundreds of available plants. To the rock-builder the crevice or fissure in the rock should be regarded as among

The Greatest Assets, those purposely indulged-in phases that lend themselves so admirably to the planter, and which in due course should glitter with the choicest of gems. A most elementary study of the root systems of a few alpinists will reveal how much the crevice or fissure is to the plant, or, to put it more accurately, how the plant through centuries has adapted itself to

SAXIFRAGA OPPOSITIFOLIA IN ITS NATIVE HAUNTS.

where it is the practice to buy the victims alive. I am strong upon the point—though I hope not too strong—because of its danger and because of the reckless way the thing is both recommended and done. Even as I write a book is open before me showing in detail the construction of this plant-starving arrangement, where every rock is a capstone to the one below it, a roof, a tile, shooting away the moisture and ensuring that powdery, inert dryness which renders plant-life an impossible thing. One is pleased, too, to note that in the main such useless projections find no place in the newly-executed rock garden at Wisley.

Large Rocks and Crevices.—In our dealings with the larger rock masses two items of the highest importance should be kept in view, viz., ensuring a great variety of aspects and the charging with soil and rocky *débris* each and every crevice as it is formed. One of the greatest charms of a rock

such environment. To a few plants—the woolly and tufted *Androsaces* and the most diminutive of the *Dianthi* and *Saxifrages*—such things border on the essential, chiefly because of their impatience of soil, soil dampness and richness, and which is increased because of the fog and humidity prevalent for weeks, it may be, in lowland gardens. Hence such positions constitute both a safe and a right place, while the root-fibres far away in the cool recesses of the rock know nothing of the vicissitudes prevailing without. In every thoughtfully-arranged rock garden there should exist a

Damp or Wet Corner or Bay, since all alpinists are not of the crevice tribe. Not a few, indeed, of the plants from the high altitudes of the Himalaya are virtually bog plants, lovers of moist and rich soils, and while exquisite in their beauty and among the more easy to cultivate, our rock garden should contain a place for them. One has but to

recall many Primulas, Meconopsis, Dentarias, Trilliums and Cypripediums to get an idea of their wealth and variety, while even such as *Anemone nemorosa robinsoniana* and *A. n. Allenii* simply glory in such places. The only way to secure the damp and shade in which such things delight is to form a bay with rocks around and, by arranging for a depression in the soil—anything a few inches below the ordinary level—ensure a more uniform degree of moisture and coolness for the roots than would be otherwise possible. The high rocks around would at once afford shelter and shade, and may be utilised for *Ranondias* and not a few of the alpine Primulas of the *viscosa* and allied sections. To ensure the continued moisture of the colony, water should be laid on by the aid of obscured perforated pipes capable of being utilised at will. There should be an efficient drainage of potsherds, stones or brickbats, and these covered with turves set grass side downwards; then a bed of loam, leaf-mould and sand in nearly equal parts and 1 foot in thickness, or, if needs be, a small colony wholly of peat and leaf-mould. Another little bit might be of sphagnum moss and spongy peat for Sundews and *Sarracenias*, while the dampest of sandstone blocks could be studded with *Pinguiculas*, which ever claim attention. In this way the damp corner can easily be made one of the most interesting and enjoyable places the rock garden contains. E. H. JENKINS.

(To be continued.)

SAXIFRAGA OPPOSITIFOLIA IN ITS NATIVE HAUNTS.

THE characteristic feature of the highest rock-falls or stone slopes in both the Bernese Oberland and the Valais is the purple Saxifrage. When all but the dwarfiest natives of the Higher Alps, such as *Androsace glacialis* and *Ranunculus glacialis*, have been left behind, and we come upon rugged desolations of weathered rocks—strewn over the mountain-side in the utmost confusion—then there greet us vast masses of the dark green foliage surmounted by the purplish crimson flowers of *Saxifraga oppositifolia*. Here in its native habitat it grows among the decomposing stone in great undulating cascades, mantling the boulders with its minute leaves in such immense profusion as to entirely obliterate them in many places, despite the rough and tumbled character of the situation.

From the natural conditions which prevail in the mountains, we may, I think, draw the conclusion that it would thrive best in the garden if we provide it with deep, gritty rubble into which it may root, copiously supplied with fresh water during its growing season. The illustration on page 603 is from a photograph taken on the Augstbord Pass, a little over nine thousand feet high. REGINALD A. MALBY.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Mrs. W. T. Smith (Japanese).—A fine exhibition type of the purest white, with broad and crisp florets. To all-sufficient size is added a refined quality. From Mr. A. Smith, Roehampton.

Chrysanthemum Miss May Fox (Japanese).—Handsome flower-heads of large size and with long, drooping florets. The centre of the flower is greenish at first, but later becomes almost pure white. From Messrs. H. J. Jones, Limited, Lewisham, S.E.

symmetrically built, fragrant, and with long, self-supporting stems. The pot plants shown evidenced considerable freedom of growth. There was not a faulty calyx in the whole exhibit. From Mr. William Lawrenson, Yarm-on-Tees.

Carnation Mary Allwood.—Obviously a Britisher bred and born, and a flower of high excellence withal. The shapely-petalled flowers, their rounded outline, all evidence the home-raised article. The colour in this section is quite new. We call it rose salmon, as in this respect it is virtually a counterpart of the border variety *Queen Mary*. If a cropper—we have not yet seen the plant—there is a future in store for it.

Carnation Salmon Enchantress.—This is all that need be said of a sport having all the attributes of the most popular Perpetual-flowering Carnation ever raised. The name colour is good and descriptive, and—it is welcome. These were exhibited by Messrs. Allwood Brothers, Hayward's Heath.

Begonia Eclipse.—A semi-double variety of salmon rose colouring.

Begonia Scarlet Beauty.—An exceptionally vivid and striking bit of colour, quite new in the winter-flowering race.

Begonia Splendour.—Intense rich crimson, and, like the last, with moderately large flowers profusely borne. An acquisition by reason of its colour, which is most effective.

Begonia Lucy Clibran.—This is a larger-flowered variety, quite novel in colour, too, which is salmon, shading to buff or palest orange. Distinct and beautiful. The whole of these belong to the winter-flowering race, are most vigorous and free in habit, and profuse and abundant in their flowering. These were exhibited by Messrs. Clibran, Altrincham, Cheshire.

NEW ORCHIDS.

Cypripedium Elatior.—This is a most beautiful *Cypripedium*, derived from the intercrossing of *C. leeanum* and *C. Baron Schröder*. It is not large, but an improvement upon the latter parent in all its parts. The individual flower is almost round, the dorsal sepal being white and prettily marked with deep violet purple, while the pouch and petals are brownish with a few spots near the base. First-class certificate. Exhibited by F. Menteith Ogilvie, Esq. The plant carried four well-developed flowers (see illustration.)

A first-class certificate was also granted to the charming *Lalio-Cattleya Bella Orchid Dene Variety*, shown by Mr. E. H. Davidson, Twyford.

Awards of merit were made to *Lalio-Cattleya Scylla*, exhibited by F. Menteith Ogilvie, Esq., and to *Cypripedium Latonia*, from Lieutenant-Colonel Sir George Holford, K.C.V.O.

The foregoing awards were made on November 19 at the meeting of the Royal Horticultural Society.

CYPRIPEDIUM ELATIOR, A NEW AND BEAUTIFUL HYBRID.

Chrysanthemum Audrey (Single).—A very handsome yellow-flowered sort, the shade rich and telling. From the Manor House Nurseries, Cardiff.

Chrysanthemum Michael Harrison (Single).—A showy and attractive variety of crimson bronze and gold colouring. Under artificial light the effect would be brilliant in the extreme. From Mr. E. Harrison, East Grinstead, Sussex.

Carnation Snowstorm.—A pure white variety of great excellence florally, and with other good qualities also; indeed, we should not be far wrong in placing this near the topmost rung of Perfection's ladder. It is a fringed-petalled variety, highly and

GARDENING FOR BEGINNERS.

HOW TO PLANT FRUIT TREES.

THE cultivation of fruit trees has been practised for many generations, and no garden worthy of the name is considered complete without a few examples. The remarks made below about planting applies with equal force to all fruit trees, although for an amateur with a small garden there is no fruit so profitable and useful as the Apple; but if he should happen to have a wall, cordon Pears may be grown, or a fan-trained Plum while for a wall with a north aspect the Morello Cherry is unequalled. In the illustration is shown a pyramid Apple tree, the Keswick Codlin variety, which is about six years old, and full of spurs and fruit-buds. Such a specimen can be purchased from 7s. 6d. to 10s. 6d., and, of course, smaller examples can be secured more cheaply; but for a grower who requires quick returns, the type of tree depicted on this page is the best to purchase.

It will be noticed that it possesses a mass of fibrous roots, which are very essential to its future welfare, and the white band just above the roots should be on a level with the surface of the soil when planting is completed. This operation can be done from the end of October until April, but it is advisable to have it finished by the end of January when possible.

First of all, the position should be chosen, and where several trees are to be planted it is best to measure the length of the plot, so as to have them in a straight line and equal distances apart. Each station may be marked with a stick or pole. The usual space between pyramids is 3 feet or 9 feet from tree to tree and 12 feet between the rows; but if only a single row is wanted, as is often the case with an amateur, the distance between the trees may be less. It should be borne in mind, however, that no advantage is gained by very close planting, for light and air are two of the most important factors in fruit culture.

Trenching not Essential.—Some advocate an elaborate system of trenching the ground twelve months or so beforehand, but I say emphatically that this is not necessary, because the Apple and its near relatives will thrive and produce good crops in ordinary garden soil. Under such conditions short, hard wood is made and plenty of fruit-spurs; while what is known as root-pruning is seldom required. When the trees are carrying a

large quantity of fruit, it will be found expedient to thin slightly, and mulch the base of the tree with partly-rotted manure.

to sink a little as time goes on, and deep planting must be avoided. Having got the hole ready and the tree therein, begin to cover the roots with fine soil, and as the operation proceeds lift up the top fibrous roots and then add more soil; by this method they are brought near the surface. It will be necessary to lightly tread the soil around the tree to make it firm, while it may require a stake to hold it in position, especially in an exposed situation, till well established.

Regarding subsequent treatment, keep the ground frequently hoed and free from weeds, and should the summer prove exceptionally dry, a good watering occasionally will prove of considerable benefit. The subject of whether to prune or not to prune the first year is a controversial one, but, speaking from experience, I should certainly defer any pruning till the second season. S.

A PYRAMID APPLE TREE FURNISHED WITH FRUITING WOOD AND FIBROUS ROOTS. NOW IS THE TIME TO PLANT.

When planting, always make the hole large enough to spread out all the roots to their fullest extent, and before placing the tree in position break up the soil at the bottom of the hole with a fork, which will prevent the accumulation of water near the roots, particularly in low-lying districts. As a general rule it can be easily seen how deep the tree was planted in the nursery, and this fact can be safely taken as a guide when arranging trees in their new quarters, but this surface mark should be just above the soil, for the tree is sure

spring. Swanley White is an excellent double white variety.

Violets should be more largely grown in pots. A shelf in a cool greenhouse is an ideal place for the plants during winter. They present no cultural difficulties, and pots of Violet Marie Louise when full of flower are delightful. Failure may sometimes be traced to the use of a too heavy or rich soil. Ordinary good garden soil, with a little leaf-mould and soot added, forms an ideal rooting medium for Violets in pots. COLIN RUSE.

WINTER TREATMENT OF SWEET VIOLETS.

PLANTS growing in frames should be examined and all decaying leaves, old flowers and other extraneous matter removed. A little soot may be stirred into the surface of the beds. This will act as a slight stimulant, and also help to keep injurious insect pests at bay. In applying outside air to the plants, the weather conditions must be considered. On fine clear days advantage may be taken to remove the lights. Air and light are most essential in the healthy development of the plants. During showery weather the lights may be raised so as to admit air, providing the force from wind is not too strong to court disaster.

During spells of severe frost the sides of the frames should be banked up with long stable manure, and mats, Bracken, or straw placed over the lights.

For continuous winter flowering and general hardiness the variety Marie Louise is difficult to beat. Princess of Wales is a popular large-flowering single, producing abundance of flowers during

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Frames.—The cuttings of such plants as Calceolaria, Pentstemons and other summer-flowering plants that are none too hardy must be fully protected during spells of frosty weather. The frames should be uncovered whenever possible to admit light and a little air. During mild weather remove the lights entirely and stir the surface soil with a pointed stick, and any plants that show signs of getting leggy should have the points of the growths carefully removed. Violas ought not to be coddled, but need protection from heavy rains and snow. Should frost lift the cuttings out of the ground, these ought to be made firm again.

English and Spanish Irises.—If the planting of the bulbs has not already been done, the earlier these are placed in the ground the better. For cutting both sections are invaluable, and the cheap rate at which they may be obtained need not deter anyone from having them and planting freely, either in rows for cutting purposes or for the embellishment of the border. Nothing is gained by allowing the plants to remain on one site too long, and once in three years they will pay for lifting and replanting on a new site.

Lawns.—While the weather is open, any alterations necessary in the groundwork should be undertaken. It frequently happens that the edge near to a path or drive becomes patchy or worn. This may be removed and replaced with inner turf. New turf may then be used to fill the intervening space. Lawns that have become weak will be considerably benefited by having a good sprinkling of fine soil strewn over them, but defer sowing seed for another month or two. Avoid walking and other traffic over them in wet weather as much as possible, but frequent brushings and occasional rollings when not too wet will prove of immense benefit.

Plants Under Glass.

Perpetual-flowering Carnations.—There are several devices for staking that minimise the amount of time and labour taken up by the old method; but when the old-time system is followed with neat strands of twisted raffia, each growth should be separately secured; otherwise, when cutting the blooms, the growths dependent upon each other will need re-supporting. Carefully disbud the blooms as soon as the side flowers are large enough, and assist the plants with applications of soot-water and manures both in liquid and patent form. The time has arrived when a batch of cuttings may be inserted for next season's early flowering. Select vigorous young side growths about three inches or four inches long, pull them out cleanly and insert without any further making in sandy soil in a close pit, propagating-frame or a warm greenhouse where they may obtain plenty of light.

Poinsettias.—Late plants now developing their bracts and in comparatively small pots will greatly benefit by manual assistance. The flowers of these will last much longer in a cut state if the ends of the stalks are sealed by being held in a gas flame or otherwise burnt to stop them bleeding.

Azalea indica.—A few plants of the variety Deutsche Perle will be generally useful if brought along and forced into flower in a warmer house. The plants must not be allowed to become dry at the roots, and a little bottom-heat, plenty of light and a humid atmosphere, with occasional syringings with chilled water, will considerably hasten their development.

The Hardy Fruit Garden.

Fruits in Store.—These should be frequently examined and none but the soundest of the late-keeping varieties retained. Handle as carefully as possible, and take advantage during inclement weather to attend to this important work.

Pruning Orchard Trees.—The pruning of large trees in orchards is frequently neglected. The work of pruning need not be delayed any longer. By far the best means of accomplishing this work is by the aid of a pair of long pruners, except for large wood, which must, of course, be removed by the aid of a saw. Spur back all the growths on the branches, leaving about two-thirds of the leading growths if there is room for extension.

Where the boughs are too thick, remove the weakest entirely, and if very bad, rather than be too severe, extend the operation over another season. To obtain good quality fruit, overcrowding must be guarded against. Collect all the prunings and burn at once.

Fruits Under Glass.

Tomatoes.—The plants that are fruiting under glass must be very carefully watered at this season, as growth is comparatively slow. Just a little sprinkling of rich fine soil on the surface of the pots will be found to stimulate root-action. Keep the atmosphere fairly dry and buoyant by ventilating whenever possible, also a circulation of heat in the pipes.

Cucumbers.—See that the beds, especially near to the hot-water pipes, do not become too dry. Keep the foliage from becoming congested by timely thinning and regulating. The foliage should be syringed once or twice daily, as the weather permits, with water warmed to the temperature of the house. As soon as the fruits attain sufficient size, have them cut and the stalks immersed in a little water.

The Kitchen Garden.

Cauliflowers.—Take every opportunity of keeping the young plants pricked out in cold frames, well aired, as with the time of year approaching they may perforce be covered up for an indefinite period. Make a sowing in heat of a quick-maturing variety, and as soon as large enough prick out into shallow boxes.

Lettuces.—The same remarks apply to this crop growing in frames. Keep as healthy as possible by removing any yellowing leaves, and fill up any gaps with young plants. Lettuces may be sown and allowed to grow fairly thickly in boxes, cutting in the same way as Mustard and Cress, when these will be found most useful for salads.

The Shrubberies.

Ornamental Brambles.—There are a few species of Rubus with very ornamental stems, and where space permits, a bed of them at this season is very attractive. One of the best we have is Rubus giraldianus, of fairly recent introduction and one of the showiest. R. incisus and R. biflorus are two others with bright stems. The last year's growth may either be cut away now or, better, left till young growth commences from the base again in spring, as the farina is apt to become rubbed off if interfered with now.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

The Latest Flowers.—Cut any sprays of the latest Asters, such as Tradescanti, and Solidago Shortii still flowering. They will remain fit for vase furnishing if preserved in a cool place for a few weeks. Conclude the planting of any belated material at once, so that the borders need not be disturbed again till the turn of the year.

Snowdrops.—Under trees the tips of the growing points of Snowdrops are evident about this time, and it will improve the appearance of the masses, as well as be beneficial to the plants, to just cover the surfaces with some finely-sifted rich compost.

Narcissi.—If the ground is not in fit condition to stir with a hoe, it may be well scratched with a rake, which is of as much value culturally, the point being to aerate the soil and prevent the growth of low forms of vegetation on the surface, which takes place on certain soils at this time of year or when the atmosphere is more than usually damp. Beds of other bulbous plants should be treated in a similar manner.

Protecting.—This is as late as it is safe to leave applying protecting material to any plants which are not absolutely hardy. A simple and efficient protection is afforded by a layer, more or less thick, of flaky leaf-mould, or, where it can be had as a substitute, Cocoanut fibre refuse, both of which are clean and unobjectionable.

Roses.—These are afforded protection about this date. The material used is soil, about two spadefuls being heaped round the stem of each.

Manure of the kind usually employed causes here a soft growth in summer, and, apart from that, the beds, while it remains, are unsightly objects.

The Hardy Fruit Garden.

The Fruit-Store.—Up till now the fruit-room has been freely ventilated, so as to allow the odour from Apples to escape. Now that winter will soon set in, the windows are closed and means taken to keep out frost without having recourse to artificial heat to keep the temperature at as equal a point as possible. The less fruit is handled the better, but a sharp look-out must be kept for decayed fruits lest they contaminate others.

Pruning.—There is no special hurry to prune apart from its facilitating other work, and, once done, the ground about the trees can be cultivated. Usually trees are left too crowded, the shoots of the past season being cut back without considering that this method is sure to overcrowd the branches with useless spurs. It is imperative not only that these should be reduced to proper dimensions, each with a few buds only, but that they should be wide enough apart to allow of no overcrowding.

Canker.—Wherever this is seen it should be cut clean away into sound wood, and the parts removed and burned. Some varieties canker so badly in some soils that it is futile to give them room. Others on which canker fixes may be cured by spraying and by extra feeding on the surface. The stock of certain varieties seems to have a predisposition to canker.

The Vegetable Garden.

Ground-stirring.—Before winter sets in, the bare spaces between rows of Cabbages, Lettuces, Scotch Kale and Spinach may be surface-stirred with broad-pronged forks. This is particularly beneficial succeeding heavy rains, after the moisture has partially drained away.

Jerusalem Artichokes.—The crop is better lifted and the best of the tubers stored than left till spring. A new plantation of the medium-sized tubers may be made at once or delayed till spring. Deeply-worked, profusely-matured ground is essential, and the ground occupied by the current year's crop should be similarly treated before the succeeding crop is planted.

Mustard and Cress.—Where these are in request, small sowings should be made at intervals of every four or five days. The soil used should be rich, but need not be more than an inch deep, and saturated with water before sprinkling the seeds thickly over the surface. Cover with brown paper and put in a hot place, removing to a cool structure when the germination is complete. Use fresh soil for each crop, and cut the stems with a pair of scissors.

The Plant-Houses.

Bulbs.—Hyacinths and Tulips will force freely now if the precaution is taken to keep them always fairly moist in a temperature not exceeding 65°, and in the meantime in the dark in order to draw up the stems. The Tulips need not be uncovered till the flowers are well advanced, a few days' exposure bringing the colours all right. Narcissi must be brought on in a temperature 10° lower, but otherwise under similar treatment. It is essential for early forcing to grow only those varieties which experience shows are sure to succeed.

Zonal Pelargoniums.—Do not allow these to grow too much. It is a commendable practice to pinch the point of each shoot just beyond where new flower-stalks are springing, which keeps the plants dwarf and at the same time causes the flower-truss to expand to larger proportions than if the stopping were not done. A very little sulphate of ammonia dissolved in the water adds brilliance to the colour of the flowers. Plants full of bloom are valued for house decoration when massed, but they must be frequently changed, else the foliage yellows and the plants are spoiled for further use for the season.

Coverings.—During cold snaps coverings laid over the glass of pits are much to be preferred to extra firing for such things as Crotons, Dracenas and other tender plants, the foliage of which suffers in low temperatures. Coverings of every kind lose much of their value if used wet or damp, and means should be taken to dry them thoroughly every time after using. R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PLANTING MICHAELMAS DAISIES (Ilex).—Michaelmas Daisies may be planted at any time between November and the end of March. Take the clumps up and divide them into quite small portions, for better results are always obtained from small plants made up of a few branches rather than from large old plants with dense masses of stems.

SWEET PEAS (Surrey).—If the cow-manure is thoroughly rotted, it should be preferred to that from horses for your soil. Cultivate as deeply as you possibly can and work the natural manure into the second spit. Into the top mix basic slag at the rate of 5oz. to the square yard and kainit at 4oz. to the same area, preferably before the end of December. The other things which you name will be better used as stimulants when the plants are in full progress.

BELLADONNA LILY NOT FLOWERING (Col. F. W. B.).—The only reason we can advance for Amaryllis Belladonna not flowering as usual is that the weather last spring was not very favourable to growth, and the weather later in the year was unfavourable to ripening. We have heard of other failures this year. Possibly your plants will flower quite well next autumn.

PEONIES (Rema).—We do not recommend the watering of Peonies during the winter season in a general way, though it is almost impossible to pay them too much attention during that period in respect to liquid manure. That is to say, it may be applied once every ten days during open weather, and in the case of light soils more particularly will leave its mark on the subsequent growth of spring. They, again, in the spring of the year, and when much dry weather is experienced between April and the flowering season, copious waterings should be given to develop growth and flowers.

POLYGONUM BALSCHUANICUM LEAVES DISEASED (G. W.).—The leaves of your Polygonum are injured by mildew, which has probably resulted from the recent cold and wet. If not attended to, the disease is likely to appear again next summer. You cannot do better than spray your plant at once with Bordeaux mixture, prepared as follows: Take 3lb. of copper sulphate and 2lb. of quicklime. Dissolve the copper sulphate in a little hot water in a wooden vessel; then in another vessel slake the lime. Pour the lime-water into the sulphate and make up to twenty-five gallons with clear water. Stir well and use. After the spraying, prune the branches back and burn the prunings. Next spring, when the leaves are bursting, spray the plant twice, at intervals of a fortnight, with the same mixture. This will kill any fungus spores which may be present. The plant would flower better in a sunnier position.

EASILY-GROWN HERBACEOUS PLANTS (A. A. L.).—Without knowing for what purpose the plants are intended, it is not easy to give a satisfactory list, though the following are all good and of easy cultivation: Adonis amurensis vernalis, Anemone Pulsatilla, Arceuthobium, Aster subcæruleus, A. Amellus, A. alpinus albus, A. a. roseus, Anemone sylvestris, A. japonica alba, A. J. rosea, Aquilegia Skinneri, A. chrysantha, A. cærulea, Arabis alba flore pleno, Armeria plantaginea rosea, Aubrietia Dr. Mules, A. Moerhousii, A. Fire King, Campanula persicifolia alba plena, C. p. alba coronata, C. Hendersonii, C. carpatia Riverslea, C. c. alba, Primula Sieboldi, P. bulleyana, P. pulverulenta, P. rosea, P. cashmiriana alba, Saxifraga bathoniensis, S. cordifolia purpurea, Gypsophila paniculata, G. p. flore pleno, Geum Heldreichii, Helenium cupreum and Hemerocallis Dumortieri. If these are not suitable, please write again, stating your requirements more definitely.

TREES AND SHRUBS.

CLIPPED YEW TURNING BROWN (Ilex).—We cannot suggest a reason for the upper part of your Yew tree turning brown, unless some injury has occurred to the branches below the point where the discoloured leaves begin. If you examine the plant, you may easily ascertain whether such is the case by removing a little of the bark with a sharp knife. If the bark appears fresh and full of

moisture, then the falling and browning of the leaves can only be due to some local condition, which may not be of a serious nature; but if the cut surface appears brownish and dry, there will be no possibility of saving the affected parts. It is not advisable to feed too liberally if the plant is growing in a border.

PRIVET HEDGE (A. B. C.).—A hedge of Oval-leaved Privet ought to answer satisfactorily in the position you describe. Both horses and cattle will eat Privet if allowed, but if there are no fields adjoining, we do not think that cattle passing along the road would cause injury. A Holly hedge would have the best appearance, but it would be more expensive and take a longer time to grow to the desired height and thickness. Privet has one failing, namely, it is more easily broken by boys or animals than such things as Thorn and Holly. You will, however, be able to decide whether a very strong hedge is necessary or not.

ADVICE ABOUT A CRAB APPLE TREE (Ilex).—The fruits sent for determination appear to be those of *Pyrus Malus coccinea*, although they may belong to one of the many varieties of Crab Apple, which show very small variations from each other and have no distinguishing names. From what is said about the condition of the trees, coupled with the condition of the roots sent for examination, we have no hesitation in saying that the plant is dying fast, and that there is no possible chance of its recovery. The sections of roots are dead and full of fungus, and we suspect that the same fungus is present in the trunk. The best plan would be to remove and burn the tree and its roots, and start again in a different place with a young plant.

COPPER BEECHES ATTACKED BY BEECH COCCUS (Rev. R. W. C. H.).—Your Beech trees are evidently infested with the Beech coccus (*Cryptococcus fagi*), which is a very unsightly disease, although it is doubtful whether it does the amount of harm which is often credited to it. Beech trees which are sometimes said to have been killed by coccus have really been killed by fungus, the coccus being a secondary consideration. However, it is a good plan to clean the trees, and as you apparently have not many specimens, you had better have them scrubbed with a stiff scrubbing-brush with a paraffin wash. The wash may be made by taking 2lb. of soft soap and dissolving it in two gallons of boiling water. Into this pour a gallon of paraffin, stir with the soapy water until a creamy liquid is formed; then make up to twenty gallons with warm water. While the scrubbing is in progress, keep the wash well stirred. For spraying purposes, 2lb. of caustic soda, 98 per cent., may be added. The mixture is very penetrating, and it should only be used through a spraying-machine on a calm day, for if any of the liquid comes in contact with the skin of hands or face, it has a drying or burning effect on it. The paraffin wash causes no ill-effects.

ROSE GARDEN.

SOIL FOR ROSE-GROWING (Quizz).—The sample of soil is fairly good. It will need to be enriched with some good manure—preferably cow or pig—and if you can obtain some top soil from a pasture, we should advise you to add some of this also. Try to provide a depth of fully 2 feet of good soil, and break up the chalk subsoil; then we think you would be able to grow good Roses.

ROSES FOR PARTIAL SHADE (W. B. P.).—You must avoid planting the very double kinds in such a position. A very good dozen would be "Betty," "La Tasca," "Pharisæer," "Melanie Soupert," "Laurent Carle," "Gustave Regis," "Grace Molyneux," "Mme. Antoine Mari," "General Macarthur," "Frau Karl Druschki," "Lady Hillingdon" and "Mme. Hoste." Those marked with an asterisk would make good standards.

PRUNING RAMBLER ROSES (F. B.).—You are quite right. The growths you have marked are called laterals. You must not, however, prune them now. March is the time to do this. If the plants are too large for their position, cut out one or two of the oldest main growths, and then open out the plants in a fan-like manner if you can. The Michaelmas Daisies should be divided each year and replanted; then we think you would have very little mildew.

PRUNING A NEGLECTED ROSE (W. T. J.).—Rose Margaret Dickson is often used as a pillar plant by placing a 6-foot pole to it and tying up the growths. If you care to do this, you should cut one of the long growths down low so as to encourage basal growths, and this could be done now. Another method would be to cut away all growths except one of the main stems, and treat the Rose as a standard. The small growths at the top, if cut back hard, would break out stronger next year and would soon make a nice head. Of course, all growths coming from the main stem should be suppressed.

ROSE FOLIAGE AND RED RUST (R. H. G.).—The foliage is badly attacked by orange fungus, which has been particularly rife this year. We do not anticipate any serious injury to the plants beyond prematurely defoliating them, and we cannot advise you to do anything now save collecting fallen leaves and burning them. Next season spray early with potassium sulphide at the rate of 1oz. to 10 gallons of water, and as the leaves become harder, decrease the water to 5 gallons to 1oz. of the sulphide. Removing 1 inch or 2 inches of the top soil in winter and burning it would destroy many of the winter spores, although contagion is possible again in spring from the hedge Roses, which are frequently badly affected.

THE BEST NEW ROSES OF 1911 (Trent Bridge).—We can quite understand your desire to obtain only the best novelties that are really advances upon existing kinds.

We have proved the following to be very good: Countess of Shaftesbury, Leslie Holland, Mrs. Charles E. Allen, Edward Mawley, Mrs. Amy Hammond, Florence H. Veitch, Reuerio A. Pulfuff, Alexander Hill Gray, Carrie, Duchess of Westminster, Fernhurst, Lady Grenall, Mabel Drew, Melody, Mrs. Cornwallis-West, President Vignet, Mme. L. Baket, Germaine Chenauet, Mme. Jules Bouche, Mrs. E. Powell, Mrs. George Shawyer, Nathalie Bottoer, Mayflower and May Miller.

THE GREENHOUSE.

TREE TOMATO (A. J. V.).—The Tree Tomato (*Cyphomandra betacea*) is a small tree, reaching a height of about twelve feet. It will flourish in an ordinary greenhouse temperature in a mixture of loam and leaf-mould. The greenish flowers are produced in long, pendulous racemes, the buds being purple. The fruit when ripe is red and egg-shaped, and is quite edible, resembling a Tomato in flavour. It is a native of Southern Brazil.

MALMAISON CARNATIONS (W. R. G.).—The dead leaf-tips may have resulted from check, too much or too little water—the former most probably. The leaves, however, bear evidences of the attack of red spider, and many of the pests are present on the specimen sent. If permitted to increase, this pest will ruin the plants. You should, therefore, either dip or syringe the plants in a solution made of an insecticide and water, a wine-glassful to two gallons. Spraying with soot-water is also good, and salt and water is an excellent deterrent if used in moderation. It is, however, fatal to the plants if rashly used. A tea-cupful only of the salt to three gallons of rain-water would be strong enough, and the plants should be laid on their sides on a mat while the spraying is being done. In employing these things it is the under sides of the leaves where the pest mostly congregates, and which require to be reached if the application is to be of any service. The soil you have been using is too light; employ loam of a somewhat heavier texture and pot very firmly. The Gloire de Lorraine Begonias have been grown in too high a temperature, and have also suffered from the attacks of thrips, usually the result of too dry a temperature. We detect no fungus on the other leaf sent, and if there is evidence of disease, cut the affected leaves and burn them.

CACTI (M. R.).—You give us no idea of the accommodation available for Cacti, whether you intend to devote a greenhouse or part of a greenhouse to their culture, or purpose growing them in a sunny window. The Phyllocacti are among the showiest and most free-flowering of all Cacti, and a fair proportion of them must be included in any selection. They flower during the summer months. The raisers of these as a rule give their own names, so that, in ordering from a specialist in succulents, the better plan will be to leave the selection to him, stipulating for distinct varieties. On no account must the variety German Empress be omitted, as the flowers, though smaller than the others, are of a delightful shade of pink, and are borne in the greatest profusion even on small plants. The Rat's-tail Cacti (*Cereus flagelliformis*) is very pretty when suspended, and the long, pendulous shoots are in summer studded with pretty rose-coloured blossoms. Practically the whole of these flower during the summer; but if you have a structure where a winter temperature of 50° to 65° is maintained, you will, during the dull months of the year, be able to enjoy the bright-coloured blossoms of the different varieties of *Epiphyllum truncatum*. All the Cacti above alluded to should be so situated that the temperature of the structure in which they are grown does not fall below 45° on cold winter nights, and at that period they will need but little water. A great deal more, however, may be given during the growing season. A compost made up chiefly of loam, with a mixture of leaf-mould, silver sand and broken brick rubble, will suit most Cacti well.

KITCHEN GARDEN.

INJURY TO CELERY (Anxious).—The Celery leaves are attacked by a fungus, and nothing is likely to effectively check the pest now it has gained a hold. Picking off the diseased leaves and spraying the remainder with Bordeaux mixture may do some good; but another year see that you get fresh seeds, grow the plants as far as possible away from the position occupied at present, and spray with Bordeaux mixture at intervals if the first sign of the disease manifests itself. Do not throw the diseased plants or refuse on the rubbish heap. Burn them.

TOMATO PLANTS GONE WRONG (R. G.).—Your plants are evidently well grown and well fruited. On first examining them we suspected the cause to be an attack of fungi, but on closer inspection we are satisfied that it is not, but is the result of some cultural defect, the most likely being the too rich and too wet condition of the soil and the too humid, cold and close atmosphere. Before the border has any more water given to it, let it become fairly dry (but not dry enough to cause the plants to flag), then take off the surface soil to the depth of a couple of inches and replace with a top-dressing of loam to which have been added three pints of lime and one pint of bone-meal to the barrow-load of loam. In applying, press firmly down, and give a good watering with clear water. Ventilate freely day and night, and apply enough heat (from the hot-water pipes) to create a gentle warmth and always keep a buoyant circulation of the air. Destroy all the affected fruits and paint the partly-affected stems with sulphur and water. Those badly affected must be cut off and new stem growth encouraged by careful culture. The plants have not been scorched.

FRUIT GARDEN.

APPLE SUCKERS (*Rajus*).—The only successful way to destroy such suckers is to carefully expose the roots from which they spring by clearing away the soil, and then cut off the suckers close to the roots.

FRUIT TREES IN CLAY AND CHALK (*H. M. T.*).—Fruit trees like chalk. If your soil is trenched and a liberal quantity of well-rotted farmyard manure applied at the time of trenching, there is no reason why Apples, Pears and Plums should not succeed fairly well in such a soil, so long as it is well drained.

ESPALIER AND CORDON FRUIT TREES (*Beauty of Bath*).—We think that Pears would do very well on the west side of your espalier wire fence, and Gooseberries as you suggest on the east side. You cannot grow fruit trees on both sides of an open wire fence. The fence should be 6 feet high, and we think that fan-shaped Pear trees would cover it better for you in time and be more profitable than the cordon-trained trees. As regards the Gooseberries for the eastern aspect, we recommend double cordon-trained trees.

APPLE TREES CANKERED (*Ilex*).—From what you say about your old Apple trees we imagine that they are not a source of profit, for what fruits are produced are poor in quality. Therefore we have no hesitation in advising you to destroy them and start again with young stock. Old fruit trees often have a picturesque appearance, but it is a mistake to let sentiment step in when such trees occupy positions in gardens and orchards where the room they occupy might be given over to young trees which would bear well-developed fruit. Such trees, which are full of disease, are also a source of injury to others, for fungus spores spread from the cankered areas to young trees, and they in time become uskers.

MISCELLANEOUS.

WATSONIAS (*Alice Knox*).—You have done what is right in drying the plants off, provided it was not brought about suddenly and has not been carried to extremes. These plants do not require to be dried off like Tulips, for example, seeing that under cultivation some roots remain more or less active.

YARROW ON LAWN (*C. H. S.*).—The best way to get rid of the Yarrow (*Achillea Millefolium*), from your lawn is to pull it out. This is rather tedious work; but you say that you have not much of it. Some people sow Yarrow with Grass on lawns, as it stands the hot weather well and keeps green very much longer than grass. It is certainly a less noxious weed than the Plantain.

CHIVES AND ALMOND TREES (*W. E. T.*).—Chives are chiefly useful as substitutes for Onions when these are scarce. It is a British plant, quite hardy, and will succeed in any ordinary garden soil. Once planted, it is well not to disturb it for at least three or four years. After this time the clumps should be divided or replanted in fresh soil. They may be replanted any time between the end of October and the end of March; but towards the end of February is the best time. Your Almond trees must be growing too strong, and while this is the case the trees will neither flower nor bear fruit freely. The best way of treating them will be to root-prune the trees, cutting back all the strongest of the roots by one-third their length. The easiest way of doing this will be by lifting the trees out of the ground and replanting again immediately the root-pruning has been done.

SAXIFRAGES AND JAMES ATKINS OF PAINSWICK (*R. B. C.*).—The late James Atkins of Painswick lived for many years at Rose Cottage, where his unrivalled collection of Saxifrages and other plants attracted specialists from all parts. Entering the village from the direction of Cheltenham, the house was a little removed from the main road on the right hand. The collection of plants in its entirety, we believe, came into the hands of Messrs. Paul and Son twenty-five or more years ago. The early hardy Cyclamen, *C. Coum*, *C. ibericum* and *C. Atkinsii* were a great feature of the garden, though the choicest gem of all—and virtually a comparative weed, seeing that it travelled far and wide—was *Omphalodes Lucilia*. To such an extent was this the fact that in 1883 or 1884 the writer of the note in question was the recipient of a big clump of it, and many more like it could have been lifted at the time. Unfortunately, the plant resented interference in autumn, and equally so, probably, the often fatal error of planting such things intact in big clumps, and, without any attempt at re-rooting, pined and died a few months later. The memory of the plants in the Painswick gardens, however, will never fade.

FUNGUS ON LAWNS (*Cove*).—We presume that the fungus you refer to grows in a circle, thereby causing bare areas in your lawn. These circles are usually called fairy rings, and are often caused by a species of Agaricus. The harm is usually done before any of the Toadstools are noticed, for the white mycelium of the fungus is at work below ground long before the visible fruiting stage appears. Still, some good may be done by collecting and burning the Toadstools to check the spread of spores. To kill the mycelium the ground should be thoroughly soaked to a depth of 9 inches or 12 inches with a solution of sulphate of iron. This may be prepared by dissolving 8lb. of sulphate of iron in thirty gallons of water and applying when the ground is damp. It must be remembered, however, that it is no use applying the mixture unless the ground is thoroughly soaked. A week after using the sulphate of iron give the patches a dressing of lime, dig them over, and sow grass seed or fill up with new turf. Another way of dealing with the pest is to remove the soil to a depth of 12 inches and fill up with new soil. The old soil may be spread on cultivated land, but not on grass.

Whether using the sulphate of iron or removing the soil, take care to carry the work a few inches beyond the outer line of the circle, for the mycelium always spreads in an outward direction. The present is a good time for the work.

NAMES OF FRUIT.—*E. M. A.*—1, Marie Guise should be picked early in October and be ripe in December; 2, Winter Nells, should be picked early in October and be ready for use in December and January.

NAMES OF PLANTS.—*S. P., Denbighshire.*—1, *Begonia Dregei*; 2, *B. Ferdinand de Lesseps*; 3, *B. carinata*; 4, *B. Luzerna*; 5, *B. fuchsoides*; 6, *Nephridium molle*; 7, *Polypodium membranacea*; 8, *Adiantum euneatum Paecilii*; 9, *A. pedatum*; 10, *Asplenium bulbiferum* variety; 11, *Pteris longifolia Mariessii*; 12, *Cyperus alternifolius*.—*L. W., Hoo.*—*Phytolacca decandra* (*Virginian Pokeweed*).—*L. Barron.*—*Agathaea coelestis*.

SOCIETIES.

NORFOLK AND NORWICH CHRYSANTHEMUM SHOW.

HELD in St. Andrew's Hall, Norwich, on November 21, 22 and 23, this fixture proved to be a great success. There seemed to be no tendency (in spite of the critical remarks of some writers) to dispense with the large Japanese blooms. Here they were quite as good as ever, and some even better. Incurves and Pompons seem to be losing favour with growers; but, on the other hand, singles and naturally-grown Japanese flowers are gaining popularity. Pot plants were a good feature, and the artistic arrangement of the circular groups was very marked, as also were the baskets, vases and table decorations. Other flowers were in profusion. Fruit was a very strong section, more especially the Apples. The wet season had been evidently beneficial to the vegetables, which were in larger numbers and much better in quality than last season. Mr. Cozens-Hardy achieved a marked success with Potatoes, winning in strong competition six firsts with only eight entries.

The seedsmen of the district and elsewhere offered prizes, the classes for which were keenly contested. The trade growers contributed largely to the beauty of the display. Foremost came the firm of Messrs. Daniels Brothers, Limited, Norwich, who did themselves great credit with a fine and educational exhibit. Hobbies, Limited, Dereham, had a large show of Chrysanthemums, Roses and Dahlias, and visitors were delighted with the arrangement. Messrs. Sutton and Soos, Reading, had a characteristic "Sutton" display of vegetables and such-like. Messrs. Wells, Merstham, had a bold bank of Chrysanthemums consisting of up-to-date kinds.

In dealing briefly with the winners, we mention first the class for a circular group of Chrysanthemums and foliage plants. Here Mr. T. Notley, gardener to E. G. Buxton, Esq., Catton Hall, won for the third year in succession, and secures the cup as his own property. For forty-eight Japanese, Sir Carl Meyer was first; but the best bloom in the show was in the second prize lot from Sir S. Neumann, the variety being *F. S. Vallis*. For thirty-five blooms, T. A. Rising, Esq., was first; while for twelve distinct Sir G. Lacon took the premier award. For six blooms, one variety, white, Sir S. Neumann, with fine blooms of *W. Turner*, and also for six blooms of any other colour, with *F. S. Vallis*, took both firsts. The best incurves came from Mr. W. Chettleburgh, gardener to Colonel Rous, Worstead, his blooms of Mrs. H. J. Hygate being very fine. He also staged a beautiful bright yellow sport from this same variety which he calls *The Colonel*. Mr. H. Cockerell, gardener to G. E. White, Esq., Eaton, won the premier prize for naturally-grown flowers, also for singles. Mr. W. Hilson, gardener to Sir F. Adair, had the best collection of cut exotic flowers. Carnations were exceedingly well shown by the veteran gardener at Gunton Park, Mr. W. Allan. He can usually hold his own with this flower, as well as being a great fruit-grower. The pot plants of *Begonia Gloire de Lorraine* from Dr. Osborne, Catton, were marvels of excellence. Mr. F. Enderby, gardener to J. H. Gurney, Esq., Keswick, had the best plants of Cyclamen, and his Violets, too, were very fine.

Mr. T. Simpson, gardener to the Earl of Stradbroke, Henham Hall, distinguished himself in the Apple classes, winning firsts for a collection of dessert and for a collection of kitchen Apples. The best single dish of Cox's Orange Pippin came from Mr. W. Allan; while for a single dish, any other variety, the lot of Allingtons staged by Mr. George Davison, gardener to Colonel Petre, Westwick, were models of excellence. Mr. Davison excelled in all the Pear classes. His *Doyenné du Comice* did one good to gaze upon. Grapes were not quite so good as we have seen them. The best three bunches of Alicante came from Mr. E. Greene, gardener to Edmund Reeve, Esq., Catton Grange. Mr. W. Allan's bunch of Gros Colmar was easily first for a single bunch, and he also won first for a white bunch with a grand example of Muscat of Alexandria.

In vegetables good collections were put up by Miss Langworthy, the Hon. A. E. Fellowes and Mr. W. Chettleburgh. Mr. A. Woodhouse, gardener to Sir H. C. Engleman, Saffron Walden, had a grand lot of Carnations, such as one does not often see at Norwich. Messrs. F. Smith and Co., Woodbridge, were well represented by a lot of fine vegetables. Besides those mentioned, there were a few others who had smaller collections.

The energetic hon. secretary, Mr. C. E. Pilling, endeavoured to see everything well placed, and is to be congratulated upon the smooth way in which his plans worked.

NATIONAL CHRYSANTHEMUM SOCIETY.

AN exhibition of Chrysanthemums was held under the auspices of the above society at Essex Hall, Essex Street, Strand, London, W.C., on Wednesday, November 20, in consequence of the earliness of the great autumn show held at the Crystal Palace on October 29, 30 and 31 last. The present show was primarily to give growers of incurved Chrysanthemums an opportunity of exhibiting their flowers at their best, and also that market-growers might make a good representation of their wares to Londoners and growers generally. The meeting was a distinct success. The larger hall was filled to its utmost capacity, and the show was well patronised by the public until the closing hour of 9.30 p.m.

The groups of cut flowers from the trade were, as usual, an outstanding feature of this society's show. Mr. Norman Davis, Framfield, Sussex, again excelled, winning a large gold medal for Chrysanthemums of all types of the flower, represented by fresh, highly-coloured specimens of splendid quality. Here were to be seen grand examples of Japanese, Lady Talbot, Mrs. Gilbert Drabble, December Gold, William Turner, Frank Payne, E. G. Moetta, Edith Jamieson and its sport A. M. Falkner. Singles were splendid, notably Mensa, the new Royalty, Agnes, Pole Star and Pictor. Incurved sorts were seen in Maritana and Durbar; and Pompons by White Baby, Baby, Snowdrop and others. The new white Anemone-flowered Godfrey's Perfection was also exhibited.

A gold medal was awarded to Mr. Philip Ladds, Swanley Junction, for a charming display of Chrysanthemums set up in bold groups of cut flowers on large stands. The flowers were grown as for market, and contained many excellent specimens of such Japanese sorts as Mme. P. Radaell and its yellow sport, Mme. G. Rivol, December Gold, W. Turner, Framfield Pink and Freda Bedford. There were also good singles, notably the new Bronze-Beauty, the yellow Ethel Mortimer and Mensa. The grouping left nothing to be desired.

Messrs. Cragg, Harrison and Cragg, Heston, Hounslow, Middlesex, staged a remarkably fine group of market-grown Chrysanthemums, arranged attractively in vases. Standard sorts and novelties were freely displayed, and the exhibit well merited the gold medal awarded to it. Some of the better Japanese sorts were Freda Bedford, Mr. F. McNiece, D. Ingamells, F. Cooper, Ethel Thorp, Foxhunter, Mary Godfrey, Mrs. Buckbee, December Gold (superb) and Miss Olive Dumsday. Singles were remarkably handsome, notably Jessica, Mensa, Portia, Mrs. W. G. Patching, Lemon Queen, Edith Pagram, Pink Beauty, Mrs. W. Garner, Mrs. W. Wells and several new sorts.

A small gold medal was awarded to Messrs. W. Wells and Co., Limited, Merstham, Surrey, for a group of cut flowers set up on the front of the platform. Bold masses of the new white Japanese, Queen Mary, were the centre of attraction, and examples of F. Jolliffe, H. Luxford, William Turner and Mrs. G. Drabble were also conspicuous. Messrs. Godfrey and Son, Exmouth, had a small exhibit of their new Anemone-flowered Chrysanthemum Godfrey's Perfection, which is a flower of fine decorative quality.

In the competitive displays the most important class was that for thirty-six incurved blooms, distinct, in competition for the Holmes' Memorial Challenge Cup. There were three exhibitors, and the veteran grower, Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashstead Park, Epsom, was an easy first, showing large, well-flushed specimens in good order and condition. The more conspicuous examples were Clara Wells, Souv. de William Cibrac, H. Hearn, Eva Smith, G. H. Evans, Miss M. Lyne, W. Pascoe, Duchess of Fife, Doris Raynor, Ethel Thorp, Colonel Kekewich, Embleme Putevine, Mrs. W. H. Jones, The Egyptian, Amber Beauty (superb), Miss N. Threlfall, Le Peyton, Marjorie Shield, Mrs. G. Denyer, Mme. Vrembley and May Phillips. The second prize was awarded to Mr. J. Broom, gardener to Miss Loagworthy, Gays House, Holyport, with smaller and less even blooms; and third prize was secured by Mr. J. Simon, gardener to Mr. W. W. Mann, Ravenswood, Bexley Heath, with large, rather rough specimens.

For a vase of singles, from which the trade were excluded, Mr. Loo Thomson, Alisa Craig, Formby, Liverpool, was placed first out of six competitors with a grand lot of ideal flowers. The second prize was secured by Mr. L. Lawrence, Shoreham, Kent, also with a splendid collection of blooms.

Great interest centred around the competition for the best new single Chrysanthemum exhibited before the floral committee on this occasion. The novelty must not be a sport, and must not be in commerce. In the end Messrs. Cragg, Harrison and Cragg's Portia, a large-flowered single, was adjudged first, and well merited the distinction.

NEW VARIETIES.

Thirty-six new Chrysanthemums were submitted for adjudication by the floral committee, and apparently a high standard was observed in making awards to most cases. The following varieties were recognised:

FIRST-CLASS CERTIFICATES.

Prince of Wales.—This is a large, full, exhibition Japanese bloom of considerable substance, having broad florets of good length that recurve in fairly even fashion. Colour, deep crimson, with bronze reverse. Shown by Mr. Norman Davis, Framfield, Sussex.

Royalty.—A dainty, free-flowering single variety rather less than three inches in diameter. Florets of good breadth, neatly disposed. Colour, bright rich crimson, with yellow disc. This flower has two rows of florets. From Mr. N. Davis.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

What to do With Frozen Plants.—If plants in a greenhouse or frame have been inadvertently frozen, they should be thawed as slowly as possible. Shade the house or frame heavily and syringe all the plants with ice-cold water until all frost has been dispersed. It is sudden thawing, more than the actual freezing, that does the damage.

A Spring Show of Roses.—It is gratifying to know that the National Rose Society has decided to hold a spring show next year in the Royal Horticultural Society's Hall at Westminster. The date fixed is Thursday, May 1. The forcing of Roses is now so largely adopted that we feel sure this new venture will meet with success. The annual general meeting of the members of the National Rose Society will be held at the Holborn Restaurant on Tuesday, the 17th inst.

Mistletoe on Pear.—It is a curious fact that Mistletoe, which is a common parasite on the Apple, is rarely, if ever, found growing naturally on the Pear. At a recent meeting of the scientific committee of the Royal Horticultural Society, Sir Harry Veitch, V.M.H., sent two branches of Pear in which Mistletoe had been sown, to illustrate the difficulty experienced in getting the parasite to establish itself on that tree. In both cases the seed had germinated, but the branches had died, and they were typical of all the infections tried.

The Glastonbury Thorn.—From various sources we have lately heard of the flowering of the Glastonbury Thorn (*Crataegus Oxyacantha præcox*), and a tree at Kew may now be seen in full flower. Mr. W. E. Ledger recently showed flowers of this well-known Thorn from his garden at Wimbledon at a meeting of the scientific committee of the Royal Horticultural Society. The flowers are borne on short shoots, which have no definite resting period as in the normal form of the species. The committee could call to mind no analogous cases among Apples or Pears, and would be glad to learn of any such that may be known.

Eucryphia pinnatifida.—One is more accustomed to see this beautiful Chilean shrub in the sheltered gardens around or near the coast, where it is usually quite a success. It may assist not a few, however, to give it a trial in more inland places when it is stated that in the Royal Horticultural Society's Gardens at Wisley a handsome specimen 8 feet or 10 feet high has been flowering well during recent weeks. Of its beauty and distinctness among evergreen flowering shrubs there were never any two opinions, and to-day its more complete hardiness is but a question of position and experiment. The great saucer-like flowers are white, to which the brown anthers are in fine contrast.

Orders for Roses.—We understand that many of the leading Rose nurserymen are inundated with orders at the present time, and that it is almost impossible in some instances to cope with them as promptly as they would wish; consequently, customers whose orders have not been executed quite so promptly as usual are disposed to grumble. We would remind such that a nurseryman must, in fairness to all, execute orders in rotation, and that those who have a reputation to maintain will do their utmost to despatch the Roses at the earliest possible moment. A little consideration by customers at this the busiest season of the year would, we feel sure, be very highly appreciated by nurserymen.

Colour Pigment in *Primula sinensis*.—The current issue of the *Journal of Genetics*, published by the Cambridge University Press, contains a very learned treatise by Professors Keeble and Armstrong on the rôle of oxydases in the formation of the Anthocyan pigment in plants, Chinese Primulas and Sweet Williams being the principal kinds dealt with. Those of our readers who are keenly interested in deep scientific research would find this treatise of considerable value. Of quite another character is a long and very technical treatise by A. H. Trow on "The Inheritance of Certain Characters in the Common Groundsel and its Segregates." The principal use of this troublesome weed is to provide green food for canaries; hence no doubt this treatise will be exceptionally valuable to breeders of these birds. Perhaps we may soon have a learned and lengthy treatise on the variations and spreading characteristics of Chickweed.

Ceanothus Perle Rose.—The various sorts of Ceanothuses which flower during late summer and autumn are mostly varieties obtained by crossing *C. americanus* and *C. azureus*. All may be considered quite hardy in most parts of the country in the open, for though during severe winters the ends of the young shoots may be killed, they break up freely from the base in spring. The usual method of culture with these late-flowering Ceanothuses is to grow them in bush form in the open, though they may be also planted against a wall or fence. They bear larger inflorescences than the spring-flowering species, and the selection of colours available is much more varied. One of the best varieties is Perle Rose, which has large heads of beautiful rich rose-coloured flowers. This Ceanothus and the companion varieties comprise some of our most showy autumn-flowering shrubs, a season when flowers are by no means common in the tree and shrub department. To complete a useful selection of six varieties, the following should be grown: Gloire de Versailles, light blue; Arnoldii, greyish blue; Indigo, deep blue; Ceres, pale rose; and Gloire de Plantières, blue.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.)

Scented Chrysanthemums.—Over thirty years ago, a then old variety—Progne, a reflexed flower of a rich purple colour—was much grown, one reason for this being that the blossoms had a pleasing Violet-like fragrance.—H. P.

— Noting your remarks *re* "Fragrance in Chrysanthemums," page 578, I would like to draw attention to the claims of the pink single Ladysmith. At the recent Brighton Show, the fragrance of specimen plants of this variety was very distinctly noticeable as one walked past the rows, and I have long considered this as an additional reason for growing large quantities of this variety for cutting.—C. ASHTAD.

— *Re* a note on the "Fragrance of Chrysanthemums," November 30, page 578, by C. Turner, I remember growing a Chrysanthemum called Progne, an old favourite of mine, very sweet-scented, like Violets, deep claret in colour and a most useful variety for decorative purposes; but I have lost sight of it for years. Mrs. Langtry and Mensa, both single kinds, are sweet-scented.—W. DRIVER, Stonehouse, Gloucestershire.

The Rockspray.—Sometimes a popular name as applied to an entire genus is very misleading, though particularly appropriate to a few of the species. This is very noticeable in the case of the Rockspray, which has of late years been applied to the Cotoneaster family. No fault whatever can be found against using it in the case of many members of the genus, such as *C. microphylla*, *C. humifusa*, *C. horizontalis* and others; but when applied to such as *C. frigida*, which is really a large shrub or small tree, the reason of the name is by no means evident, and might be severely criticised.—H. P.

Winter Effects of Flower and Shrub.—In the article on this subject on page 587 by that most interesting and authoritative writer Miss Jekyll, no mention is made of the Prickly Heath (*Pernettya mucronata*). Her list is so full that the omission of this plant was the more noticeable. Was it an oversight, or does it not thrive with her? Individual plants, nicely berried, are most handsome, while a bed of plants would be still more so. The colour of the berries varies somewhat, but is usually of a deep or dull pink shade, which, owing to the very small, dark green leaves of the plant, is plainly seen. There should be no hesitancy in classing this as one of the most ornamental of our outside winter plants.—C. T., Highgate, N.

The Deciduous Cypress Fruiting.—I was very much interested in reading the notes by "W. D." and "G. G." in THE GARDEN for November 9, page 562, about the Deciduous Cypress fruiting. In the pleasure grounds of Standish House, Stonehouse, Gloucestershire, there is a nice specimen of the Deciduous Cypress, bearing fruits near the top of the tree. No doubt the Cypress naturally likes a damp situation; it is growing quite close to the fish pond, and many roots can be seen at the edge of the pond. I believe the late Mr. Richard Potter planted the tree about fifty years ago. He extended the gardens and improved the place during his long residence at Standish. I also remember seeing the Deciduous Cypress referred to by "W. D." at Syon House, Brentford, being employed in the gardens there during 1865 and 1866 as under-gardener.—WILLIAM DRIVER, Stonehouse, Gloucestershire.

Primula Forbesii as a Cut Flower.—A prolonged acquaintance with this beautiful little *Primula* has enabled me to learn and appreciate its good qualities as a cut flower. I am almost inclined to think that I like it better than *P. malacoides*, especially since I have grown both the lighter and darker shades. They blend so well together when nicely and lightly arranged in suitable vases. They always keep in good condition for a fortnight when cut, but it is only fair to say I have no gas in my house. I had an exquisite vase on my dinner-table last week. There was a sort of undergrowth of the mealy form of *P. kewensis* with a few flowers fully open, and under it, as a sort of guard petals, some Maidenhair. The top growth was all *P. Forbesii*, the darker deep ruby red ones predominating. As this was my house-keeper's arrangement, and as I knew nothing about it until it was a *fait accompli*, I feel I may say a word in its praise.—JOSEPH JACOB.

Sweet-scented Verbena for Low Greenhouse Wall.—I agree with Mrs. Earle ("Pot Pourri from a Surrey Garden") in wondering why Sweet Verbena (*Aloysia citriodora*) is comparatively seldom planted out of doors. Taking the hint from the above-named book, I have had some of these delicious little plants put out against a greenhouse wall. They survived last winter admirably, and have grown into large, healthy bushes. As soon as the frosts commence, the long stems are cut down almost to the ground and the shrub is packed with dead leaves piled up high over it, the leaves being kept in place by wire-netting. With other half-hardy plants requiring a warm wall, together with large-flowered limbing Roses, such as Reine Olga de Wurtemberg, Ards Pillar, Climbing La France, Climbing Caroline Testout, Bardou Job, &c., one can do much to beautify the ugly low walls of a greenhouse. With me the above-mentioned Roses flower almost continuously for four or five months or more, retaining their foliage until well after Christmas.—ELEANOR G. SHELLEY, Avington Park, Alresford, Hants.

Saxifraga oppositifolia in its Native Haunts.—Most interesting is Mr. Reginald A. Malby's note (page 604) and very charming the photograph (page 603) of one of the fairest of alpine gems. Though we do not all of us possess "rugged desolations of weathered rocks" over nine thousand feet above sea-level, we can grow this bright mountain plant with very considerable, if not perfect, success. In 1910 I grew good tufts of it on a southern slope of ordinary loam, the roots slightly protected by nothing more than weathered flints. However, in the drought of last year most of the tufts were scorched up. This year I have largely followed Mr. Malby's ideas and put in my plants so that their roots will have a deep root-run on the cool side of rocks of from 2cwt. to 3cwt. each. As the rocks are nearly flush with the soil, I expect that the dark green leaves will spread over them, and I only hope they will be mantled with as much beauty as those in Mr. Malby's photograph. The first time I saw *S. oppositifolia* growing wild was in Norway in the *débris* of the moraine at the foot of the Kjendalsbræ Glacier. This was not much above sea-level. This and other plants had been brought down by glacial action. Had I been able to ascend the glacier, I might have found *S. oppositifolia* revelling in "undulating cascades" on the lofty, rocky slopes of Jostedalsbræ. As it was, I brought home the few specimen plants, but they, too, were scorched up in the drought of last year.—G. H. ADDY, Ightham, Kent.

A Live Garden Shelter.—The note and illustration on this subject, page 569, issue November 9, recalled to mind some very interesting and ornamental flower-beds in a garden under my charge a few years since. The beds were circular and about four feet in diameter. Instead of living withes, Hazel sticks were used in the same manner as illustrated, a stout central stake being used in the centre to keep the whole in a rigid condition. The height of the central stake was about five feet from the ground-level. At the base of the Hazel sticks, Ivy-leaved Pelargoniums, Heliotrope and Tropæolums were planted for producing a summer display. There are other subjects just as good for this scheme, but the above were used in our case as being particularly suitable for the general bedding arrangement. Where a large number of beds of geometrical design have to be planted, as, for instance, an Italian garden, a few beds planted thus will prove invaluable.—COLIN RUSE, Lambay Island.

The Relative Value of Manures.—While travelling in Wales last summer I happened to meet an old countryman, over whose garden I was shown. In the course of conversation with him I enquired as to what manure he used to obtain such splendid results. His answer was: "Why, horse-manure! I don't believe in your cow and pig manures." I, naturally, enquired why, and this was his logical answer: "A pig is fed to make good meat, a cow to make meat and also milk, but a horse simply feeds to live. Therefore in my thinking horse-manure is the best, owing to the former two animals extracting more goodness from their food than does a horse." I give you the above, of course, for what it is worth, and it would be interesting to hear what your readers think. From what I saw of his produce it was excellent in every respect. He also showed me ten first and eleven second prizes gained in 1911, and I have heard since that he took nearly the same number this year.—B. A. B. [We publish the foregoing letter as indicative of an opinion that is certainly original. We do not think, however, that it is quite as logical as our correspondent thinks. On heavy soil horse-manure would be the best, but on that of a sandy character we would prefer cow or pig manure.—ED.]

Shrubs for Smoky Towns.—A residence of some years in a confined and smoky district of London convinced me that, as stated by your correspondent "W. D.," page 602, evergreens should be planted, but sparingly. The one, however, that gave me the greatest amount of satisfaction is not mentioned, namely, *Fatsia japonica*, or *Aralia Sieboldii* as it is so often called. This, which grew too large for indoors, was planted out, and a very handsome and much admired specimen it made. It did not resent the confined quarters as did many plants, and in time it formed a handsome clump of many stems, all clothed with noble leafage. After winter was over, the leaves were thoroughly sponged with warm soap and water, which, owing to the large leaves and their leathery nature, was really a far less formidable task than may be thought. The only trouble was late in the spring, just as the young leaves were developing, as they were then very liable to be attacked by green fly on the under sides; but syringing with an insecticide cleared them off. The early autumn display of flowers was also very attractive. I write in the past tense, as my present abode is more favourable to plant culture. The common Fig is another first-rate subject for London gardens, not as a fruit tree, but as a bold ornamental deciduous shrub.—H. P.

Solanum crispum (the Potato Tree).—This plant should be grown wherever beautiful flowering shrubs are valued. It is much hardier than is generally supposed, and owing to its quick growth soon forms a large bush. It can be planted in the border in favoured localities, or on a wall where some protection is deemed advisable. A plant on a wall at Lambay has grown from a single shoot a few inches in height to a specimen 8 feet or 9 feet in diameter and 5 feet in height during the past season. A good loamy soil suits this subject.

Abutilon vitifolium.—Seedlings of this plant are frequently disappointing, the colours of the flowers often being very inferior. This plant thrives in the garden at Lambay, both in the open borders and as a wall plant. It is easily increased by cuttings taken from the half-ripened wood in the autumn. Cuttings should be inserted firmly in a sandy compost, and placed in a shady corner of the greenhouse until rooted. Pot off singly and plant out during the following season.—C. R.

A Pretty Autumn Combination.—On page 574, issue November 16, "S. T." has a very interesting note on the above. The *Kniphofias* are, generally, among the most showy of all border plants, and their flowers generally harmonise well with the autumn tints in foliage. The plants are very free in the production of flowers; I have had large clumps which bore flowers during every month of the year. I recently saw a very effective combination of plants in a large border in the grounds of Highcliffe Castle, near Christchurch, Hampshire. *Prunus Pissardi* showed well above handsome clusters of Pampas Grass bearing lovely plumes, and intermixed with these were *Kniphofias* flowering freely. The effect was bold, harmonious and pleasing to the eye, and it was enhanced by the background of large evergreen and deciduous trees and the grey walls of the castle itself.—G. G.

The Californian Tree Poppy.—No plant has given me greater joy than the Californian Tree Poppy, or *Romneya Coulteri*. Its large, white, satiny flowers, produced at more or less irregular intervals from June to September, are always a source of admiration. Occupying as it does a sheltered corner against a wall where it is exposed to the full sun, it is a most desirable plant for the position. I find that it resents disturbance at the roots, like most, if not all, other members of the Poppy Order, and it is most satisfactory to purchase plants in pots for planting. In severe weather this plant needs the protection of some light and dry material, such as Bracken or leaves. In hard winters it may be cut to the ground, but signs of life soon follow, as it invariably breaks away from the base in spring.—S., *Berkshire*.

FORTHCOMING EVENTS.

December 9.—United Horticultural Benefit and Provident Society's Committee Meeting.

December 11.—North of England Horticultural Society's Meeting at Leeds. East Anglian Horticultural Club's Annual Meeting.

December 16.—National Chrysanthemum Society's Executive Committee Meeting at Carr's Restaurant, Strand, at 7 p.m.

December 17.—Royal Horticultural Society's Committee Meeting (no exhibition).

December 19.—Linnean Society's Meeting.

December 30.—Hereford Fruit Show (two days).

January 7, 1913.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster, S.W.

FUMIGATING WITH CYANIDE OF POTASSIUM.

[In Answer to a Correspondent.]

THE formula for the production of hydrocyanic acid is one part cyanide of potassium, two parts sulphuric acid and four parts water. As an insecticide, 1,000 cubic feet of atmospheric space is usually employed as the unit to be filled, and for ordinary greenhouse purposes as low an application as half an ounce of cyanide, 10z. of sulphuric acid and 20z. of water may be used. For mealy bug these must be doubled or even quadrupled if the vegetation is at rest. The stronger the acid, the shorter time must the plants be allowed to suffer exposure. Twenty minutes might do no harm with a strong application, while forty minutes might result in death to very tender plants. The great value of a light application, such as half an ounce or 10z. of cyanide, is that no plant suffers; but the time must not be limited. That is, the house cyanided at night need

exceeding 50°, should be aimed at during the period of cyaniding. The materials are all cheap, but they vary—even water! Before now the writer has had to pay insurance on the sulphuric acid before the railway company would carry it. Near a large town this would not be asked. Beware that no one breathes the fumes of the acid, as it is a deadly poison. In conclusion, be sure the dimensions of the house to be treated are correct. Recently an assistant brought me the dimensions of a house with almost twice the number of cubic feet the structure actually contained. R. P. B.

THE ROSE GARDEN.

NOTES ON THE NEWER ROSES.

HYBRID TEAS FOR EXHIBITION.

(Continued from page 602.)

Mrs. Richard Draper (Hugh Dickson, 1912).—This is a fine Rose. It was awarded the gold medal at the "National" in Regent's Park last year, and will, I think, become very popular. It is likely

FLOWERS OF THE CALIFORNIAN TREE POPPY (*ROMNEYA COULTERI*).

not, nor should not, be reopened till the next morning. We would strongly advise you to use only half an ounce for greenhouse plants and 10z. for such things as Palms, allowing a long exposure. The procedure is very simple. Ascertain how many thousand feet of air the structure contains. If 4,000 feet, say, use 20z. of cyanide with other materials in proportion; but the amount of water need not be limited to the exact quantity; over the quantity does not matter. Get one or more earthen receptacles large enough to contain the material, which sometimes "boils" violently, and apportion an equal quantity to each. First place the proper amount of water in each; then empty in the sulphuric acid. The cyanide of potassium having been wrapped in stout paper, quickly drop each packet into its own receptacle and escape from the structure before evaporation commences. Lock the doors securely, and next morning be cautious not to breathe the internal atmosphere till ventilated anew. A low temperature, not

to be useful as a garden Rose as well as an exhibition sort, as it is very free and has an excellent habit of growth. I saw it in splendid form at Belmont this year. There is plenty of substance in the petals, and is a particularly clean, smooth-looking flower, bright rose pink on the outside, and the inside appears of that pale silvery flesh colour generally associated with La France. The flowers are large and well formed, with a good point. Altogether a most promising variety.

Mrs. Wallace H. Rowe (S. McGredy and Son, 1912).—This Rose has not been given a fair start by the raisers. They send it out with the colour description of Sweet Pea mauve! Mauve may be all right in Sweet Peas, but we do not want it in Roses, and I do not think there is any trace of it in Mrs. Wallace H. Rowe; at any rate, not here in Hampshire. With me the plants I have grown this year have produced some very beautiful flowers. Cerise carmine pink, a combination of true colours, yet a pure self; of great size, and

excellent substance and finish, leaning strongly to the Hybrid Perpetual in both habit of growth and shape of flower, producing three or four buds at the end of each shoot and on shortish footstalks that must be reduced to one bud, which can be the centre or crown bud. I have seen no sign of mildew on the plants. A very useful back-row flower, quite distinct. It has flowered again well in the autumn, and I can recommend it.

St. Helena (B. R. Cant and Sons, 1912).—This was magnificently shown at Southampton by the raisers, and it not only secured a gold medal in the new seedling class, but a flower from a thirty-six box also won the silver medal for the best Hybrid Tea in the show—a very useful performance to stand to the credit of a new Rose for one day's work. It obtains its name not from the small island of Napoleonic fame, but from the lady the Patron Saint of Colchester, and the accent is placed on the first syllable. It is a good, sound colour, cream, with a deep blush in the centre, the open flowers reminiscent of Joseph Hill at its best, but in the half-open or exhibition stage coming with a fine point. I have not grown it,

sorts as Mrs. Herbert Stevens and Molly Sharman Crawford, to name only two, anyone can grow, and they should both be included in collections of Roses, however small.

There are, I find, about a dozen new Teas that come within the limits that I set myself in dealing with exhibition Roses, and of these exactly half come from the Newtownards Nurseries of Messrs. Alex. Dickson and Sons. The others are the products of different firms, none of whom can lay claim to more than one variety, so that Messrs. Alex. Dickson and Sons are far ahead of all competitors, and the debt that they have placed Rose-lovers under is never likely to be adequately discharged; but it sits very lightly on the shoulders of most of us, and we take the good things of the Rose world as they come without troubling anything about the obvious enquiry, "To whom do I owe this?" and acting accordingly. Here is my list of twelve. I do not think I have omitted any that can lay claim to the title of an exhibition Rose, and it is those only that I am now dealing with.

A. Hill Gray (Alex. Dickson and Sons, 1911).—The veteran Tea Rose lover after whom this Rose

Mrs. Foley Hobbs (Alex. Dickson and Sons, 1910).—The best exhibition Tea of recent introduction, most reliable in every way. The raisers call it delicate ivory white; but is ivory ever white? I should prefer to call it pale cream. It is perfect in shape, a good grower, and so easy of cultivation that it should be in every exhibitor's collection. It has won the silver medal for the best Tea oftener than any other variety this season, and for a box of twelve has frequently beaten White Maman Cochet. It has stood out among the new Teas as prominently as George Dickson has among the Hybrid Teas, and one cannot find a fault with it; sweetly perfumed and mildew-proof. It won the gold medal of the National Rose Society at the autumn show in 1910. The young flowers have a beautiful Picotee edging to their petals. Altogether one of the best of the new Roses.

Mrs. Herbert Stevens (S. McGredy and Son, 1910).—Disbudded and grown strongly, selecting only the crown bud, this Rose may claim to reach the exhibition standard. Here again I must part company with the raisers' description. I have grown Mrs. Herbert Stevens now for three years, and the "distinct fawn and peach shading in the centre of the flower" has been conspicuous by its absence. With me, if it has any colour in it that is not white, it must be termed eau de Nil, the ladies' name for a pale green. Anyhow, be the colour what it may, its beautiful shape is beyond question, and there is a refinement about the whole flower that is particularly charming, so much so that if I could grow only one white Rose, I should say give me Mrs. Herbert Stevens. I know there is Molly Sharman Crawford, and even Frau Karl Druschki might be considered by some to have claims; but Frau Karl Druschki "leaves me cold," as the Americans say, and it is only fitting she should. Was not her original name Lady of the Snows? Molly Sharman Crawford has a warm corner in my heart too, for reasons I need not here mention; but though possibly a finer Rose, she is not, I think, so beautiful. Hardy and vigorous, the only possible fault one can find with this Rose is that the flowers are not held quite erect; but here again I am not sure I would have them so. They are better as they are, the beauty of the flower half-hidden, shielded from the gaze of the crowd. No; there is nothing but refinement in this Rose, and I would not wish to alter it.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

ROSE PRINCE DE BULGARIE.

Of the many Roses recommended for autumn flowering, it is questionable whether any are capable of producing finer effects than Rose Prince de Bulgarie. The accompanying illustration shows a bed of this Rose as it appeared late in September in a Surrey garden near Weybridge. This variety belongs to the Hybrid Tea section, and is well known to produce better blooms and in greater profusion during late summer and autumn than earlier in the year. In colour the blooms are of silvery salmon, deepening in the centre to a pleasing shade of apricot. It is a delightful and distinguished Rose. From the fact that Roses are grown on a very large scale in Bulgaria for the purpose of manufacturing attar of roses, this country lays claim to the title of "The Rose Garden of Europe," and in this respect the aspiring Balkan kingdom is the envy of greater Powers. It is fitting, however, that so promising a Rose should bear the name of Prince de Bulgarie.

AN AUTUMN BED OF ROSE PRINCE DE BULGARIE IN A SURREY GARDEN.

but it is certainly worth getting, and is being sent out by the raisers at 5s. for ground plants.

White Killarney (Waban Conservator, 1910).—This has been disappointing with me. Its flowers have been too small, and I do not think it is wanted. Certainly not to be mentioned in the same breath with Mrs. Herbert Stevens or Molly Sharman Crawford, to mention two good whites.

TEAS FOR EXHIBITION.

The raisers of new Roses are turning their attention to this class, and in consequence new Teas of merit are more frequent than they were a decade back. We are now obtaining Teas of more robust habit, better constitution, and very much larger flowers. They are gradually becoming more popular, and as they improve in hardiness so will that popularity increase. They are undoubtedly the most perpetual of all Roses, the most prolific in the number of their flowers, and at the same time their perfume and colours are so varied that to anyone with a fairly sheltered garden they should make a very strong appeal. It is true some of the old varieties require very high culture and no little skill to bring the flowers to perfection; but such

is named deserved a good Rose, and I think he has got it; in fact, I am inclined to call it the best yellow Tea in commerce. Its growth is good; the colour does not fade as in the case of most yellows, but deepens in the older flowers; the scent is there, and it is not easy to find a fault with it. The contrast with the foliage is noticeable; it is, so far as I have grown it, mildew-proof, and altogether a first-class variety. I picked a beautiful flower of it on November 10, and it has been good all the season. It was awarded the gold medal of the National Rose Society at the autumn show in 1908, but was only distributed last year.

Miss Alice de Rothschild (Alex. Dickson and Sons, 1910).—This Rose is more of a bedding variety perhaps than the last named, but it has been frequently exhibited this season. It is a fine colour, deeper than A. Hill Gray, and I have yet to see a "white" flower of it. It is a good free grower and deliciously fragrant. I see it generally catalogued as a Hybrid Tea, due, no doubt, to its vigorous growth; but the raisers call it a Tea, and its perfume alone shows that it has much Tea blood in its veins. It is a good, hardy variety for a yellow.

TREES AND SHRUBS.**THE TREATMENT OF INJURED TREE TRUNKS.**

It has occurred to me that it may be of interest to other readers to know how I have treated hundreds of damaged tree trunks and diseased branches.

SHOOT OF THE MACEDONIAN PINE, SHOWING THE CHARACTER OF THE CONES.

At one time I had charge of thousands of street trees, and it used to be a very common occurrence to have one badly barked and bruised. My first duty was to trim the damaged parts of the bark and wood as neatly as possible. I would then paint them over with a mixture of Stockholm tar and sulphur of the consistency of glaziers' putty, to protect the wounds from further injury. I usually placed a piece of 1-inch mesh wire-netting round the trunk, the size according to requirements. I always found this a most effective treatment, and in time the wounds would be quite healed over.

In cases of deep holes or badly-lacerated limbs, I always made a mixture of sawdust, tar and sulphur into a stiff paste, and after the usual trimming I filled up the parts affected to the same circumference as the trunk; then wrapped round the parts treated with coarse canvas, securely tied and netted if near the ground. In this way I have saved very many valuable trees from destruction.

The loss of many street trees is often a mystery, and there are frequently other causes than an accident by collision. My experience taught me a most valuable lesson, viz., that street tree culture requires as much care and observation as any other section of horticulture, and whoever has charge of a dozen miles of trees along each side of tram-lines, and gas mains running parallel to the line of roots, must be an observant man, or he will have failures which are impossible to replace. I could give some most interesting instances of gas-poisoned trees; but my advice to all who have charge of such is to make observations between the tree spaces by thrusting a sharp-pointed steel bar well into the ground. Any gas that is escaping will follow the bar when withdrawn.

Another source of great destructiveness to trees is a fungus attack on the trunk or among the branches, particularly among Sycamores and English Elms. This disease does its deadly work often unseen and unknown until too late to remedy. Once it attacks right round either the trunk or a limb it means death; but if it is discovered before it attacks the circumference and is painted over with Stockholm tar and sulphur, it will be absolutely killed and the tree or branch saved. I have made a special study of this branch of my calling, and I know what this mixture will do. I used to make it a practice of sending a smart youth into the Sycamores and English Elms to examine the junction of the limbs to the trunk, as very often I have found strong attacks at these places. The boy would be provided with a note-book and report to me his findings. In this way very many valuable trees have been saved from a mysterious death.

Sheffield.

THE MACEDONIAN PINE.

(PINUS PEUKE.)

PINUS PEUKE is regarded as the European representative of the well-known *Pinus excelsa*, or Bhotan Pine, native of the Himalaya. For some time *Pinus Peuke* was looked upon as a variety of *Pinus excelsa*, but in more recent years it has been raised to specific rank. In appearance this stately tree is not unlike the Weymouth Pine.

It is, however, very hardy, and not so readily attacked by diseases, and for this reason we understand that the Macedonian Pine is being extensively planted in Germany in the place of the Weymouth Pine. The natural distribution of *Pinus Peuke* is limited to comparatively small areas in Bulgaria, Macedonia and Montenegro, an interesting point in view of the war now waging in these parts. In certain districts this Pine forms woods of considerable extent, while in Southern Bulgaria it appears here and there as solitary specimens from 25 feet to 50 feet in height, in association with Spruce, and with a thick undergrowth of Juniper. It is a tree varying much in height in its native habitat. In low altitudes it attains a height of 100 feet, while in the alpine zone, with *Pinus montana*, it is dwarfed and stunted in growth. This tree may be raised from seed exported from the Balkans, as is evidenced by the following extract from Vol. V. of "The Trees of Great Britain and Ireland," by Elwes and Henry: "Through the kind offices of Pierce O'Mahony, Esq., we received a large quantity of seed from King Ferdinand of Bulgaria in April, 1908. This has been widely distributed to different friends throughout England, Ireland and Scotland. Most of it was tardy in germination, and the seed came up irregularly, some not germinating until 1909."

There are several fine specimens of this tree in England, and at New there is a group of healthy trees near to the Isleworth Ferry Gate, a portion

of this group being illustrated on this page. These trees, it is interesting to observe, were raised from seed of the original importation in 1864.

ROCK AND WATER GARDEN.**ROCK GARDENS IN THE MAKING.**

(Continued from page 604.)

The Stability of the Rocks.—In the construction of the larger rock garden there is nothing of greater importance than the assured stability of the rocks. Conversely, there is nothing so disastrous as shifting or settling rock. Such settling is most likely to occur after heavy rains, and more particularly in those instances where much rock had been built up on recently-disturbed ground. The danger in such a case is not pleasant to contemplate. It might seriously affect the erection as a whole or in part, and would of necessity upset the planting and cause much work to be done a second time. Hence the need of starting from a solid foundation. To obtain such a foundation, great masses of rock must needs be buried out of sight. In that wonderful rock garden at Friar Park, hundreds of tons of massive rocks are so buried, and these, having their start on a natural rock-bed foundation, are as safe as the hills themselves. In gardens generally, a comparatively safe and solid foundation may be obtained

THE MACEDONIAN PINE, PINUS PEUKE. THIS IS A TREE FREQUENTLY MET WITH WILD IN THE BALKANS.

on gravel or clay at no great expense. In other instances adequate safety may be assured by sinking the foundation-stones deeply into firm, undisturbed soil. The gravest error of all in this connection is that of arranging rocks on recently thrown-up banks of earth. Where this is so, the rocks should be first arranged and the soil and grit supplied afterwards. In such a case the tight packing of every crevice from behind is a matter of considerable importance. For this purpose soil, brick rubble and small pieces of rock are invaluable. By wedging such a mixture into position, the roots of plants will find ample support later on.

The Naturally-Endowed Site with undulated bank or rugged, picturesque slope is in a different relation altogether, for the soil is already in position, and is stability itself. Here the operator would have to concern himself more with fashioning and so piecing together that a useful and presentable whole is assured. In such circumstances, the chief work, apart from the rock-building, would be the removal of some portion of the crude, inert soil of the bank, replacing it by more suitable material. This should be done with every stone and crevice as the work proceeds, though more particularly with those crevices whose position renders them immediately available to the planter. For such work one cannot too strongly urge the mixture mentioned above. Old mortar, broken sandstone or limestone, in pieces from the size of the fist to one-half or one-quarter that size, will be found of special value. In Nature such things play an important part by reason of their uniform coolness, and in our gardens they may be made to perform a similar function, though perhaps in minor degree. Moreover, these things nourish and sustain plant-life, hence the need for their presence in every crack and cranny the rock affords. A vacuum, whether horizontal or vertical, would, of course, be fatal to vegetation, and the fact should be writ large. In dealing with this question of rock and *débris* charged crevice, we might give more than a passing thought to

The Soil Nature Provides for her children, and how not a little of this is continually washed into position either by rain or snow, sometimes into the crevice itself, though more frequently into the very heart or tuft of the plant. Hence an alpine plant in Nature is in receipt of an annual mulch, so to say, and that by a natural process. It may be, too, that the mulch is repeated several times each year, of which the occasionally buried or half-buried examples of plants afford ample proof. Those that remain exposed are, of course, the best, not merely from the standpoint of perpetuating the species, but as object-lessons for those who have eyes to see. It is into this eternal supply of grit mingled with humus, rich as it must be in the soluble inorganic salts which are constantly being brought down from the higher slopes, that the most diminutive of alpine plants delight to root afresh, and of whose value we who garden

among such things have even as yet but the faintest idea. To a high alpine in Nature this constantly-recurring mulch is its chief food supply. For proof of it one has but to remove a tuft from a rocky ledge and view the mat of root-fibres it contains. In part this may be due to position and environment, though not entirely. The very depressed spreading nature of the tuft will show the marvellous spread of the root system in many plants, will show the ramifications of every tiny rootlet eager in the desire to embrace the moisture that is not infrequently—though all imperceptibly—associated with the rock. The same plants, too, will show us how much the rock is to them in those higher regions of the earth where, but for the rains, the mists and the snows—each and all rich in inorganic salts—these children of the mountains in these rarefied atmospheric conditions could not long survive. Thus we see how Nature provides for her own.

SILENE ACAULIS GROWING WILD ON THE ALPS.

In Lowland Gardens, and generally under cultivation, the plants are differently conditioned. We provide them with soil already rich—too rich, often enough—in vegetable matter or humus, and we see the results of our handiwork in a type of plant that, not infrequently savouring of undue vigorousness, loses not a little of that infinite beauty—dainty grace, more brilliant colouring or diminutive cushioned tuft—that so characterised it in its mountain home-life. In a word, we out-characterise certain of the flower gems of the mountain world by a generosity of treatment that probably does not make for longevity or even give to our rock gardens those brilliant colour touches that we still retain in the mind's eye. Elsewhere, in a former chapter, I touched upon the danger of soil, of soil

damp and soil richness to many high alpine having woolly tufts of leaves; and here, in a closing word upon soils, I would like to drive the point well home, to emphasise the need of more grit and less rich soil than is usually employed; more rock in a finely-pulverised form capable of being introduced into the most diminutive of leaf-tufts, there to assist in the formation and reconstruction of root-fibres, and in turn to refresh, revitalise and preserve to these plants the best with which Nature endowed them.

E. H. JENKINS.

(To be continued.)

ALPINES IN THEIR NATIVE HAUNTS.

Saxifraga muscoides.—When plant-hunting recently, at the head of the Turtmann Valley in the Valais and at an altitude of 7,000 feet, I came upon a fine mass of *Saxifraga muscoides* growing in the interstices between large pieces of rock, which had come hurtling down the alpside and had locked together in a confused pile. Here, in the accumulation of vegetable detritus, the *Saxifraga* made large "mats" of foliage, and, rising above this green moss-like carpet, the white flowers were produced in such abundance as to almost entirely obliterate the foliage.

The Cobweb Houseleek.—On the open alpside, subject to the intense rays of the July sunshine, this *Saxifraga* thrives amazingly, while on the same rocks the Cobweb Houseleek grew in downy clusters. The rosettes varied in size from the normal half inch in diameter to tiny Pea-like growths one-eighth of an inch across, and all more or less crimson in colour, owing to the fierce exposure. The *Sempervivum* appeared to grow on the bare face of rock, where the merest roughening of the surface induced a slight deposit of wind-swept detritus to accumulate.

It struck me as curious that these two plants, which we associate in our gardens as shade-loving in one case and sun-loving in the other, should be so happy in each other's company. Probably the explanation is to be found in the fact that, despite the torrid heat of the upland pastures, the soil and the partially-protruding rock masses are being perpetually moistened with the soaking snow-water which percolates so copiously down the mountain-sides throughout the growing season, while the uninterrupted grip of winter ensures that they shall be dry and not exposed to the variations of temperature which they have to withstand in our muggy climate. Many such plants, which are generally spoken of as shade or partially shade loving in our garden, but which inhabit fully-exposed positions in the mountains, would, I believe, flower much more profusely with us if planted in a sunny aspect, provided we give them a copious water supply from March to July.

Silene acaulis.—Having zig-zagged up the steep alpside to an altitude of 8,000 feet, passing multitudes of alpine gems, lavished in the utmost profusion on every hand (but which space will not

permit me here to refer to), I came upon many glorious patches of *Silene acaulis*, the beautiful, compact Cushion Pink, which at these high elevations mantles the steeper sides of almost every protruding hummock. In such positions it is so "close" and "hard" as to resemble masses of green coral, while, when the flowers open, they are so closely set as to entirely obliterate the foliage. It is interesting to trace back some of these communal growths, which, even when covering a large space, all emanate from one strong, woody taproot, which plunges down and down into the stony soil and defies extraction. The clustered growths, however, can with advantage be split up, and if two or three individual spikelets are planted deeply and firmly into a very sandy compost, kept moist and "close" for a few weeks, they make satisfactory cuttings. After the rather poor display this *Silene* gives us in the rock garden, it comes as a great delight to tramp over alpsides rendered rosy with the innumerable tufts of this pretty plant. I have found that the moraine offers the greatest chance of success with it near to London, and the variety *pedunculata* thrives very well with me, as the illustration in THE GARDEN of June 17, 1911, shows, though, of course, it falls far short of the glories of the high upland pastures.

REGINALD A. MALBY.

FLOWER GARDEN.

SOME FACTS ABOUT THE TULIP MANIA.

(1634—1637.)

THE apocryphal tales of this famous period are fairly widely known. So, too, are the sort of bargains that were sometimes made by those desirous of possessing some expensive variety when the necessary cash was short or wanting. These are the commonplaces of Tulip history or romance, and if they are not true in fact, they are in spirit, inasmuch as they illustrate in a very striking way the unreasonable and unparalleled values to which Tulips rose in the height of the mania. What actually happened was so extraordinary that it really needed no bush to excite the wonder of succeeding generations. The craze has been aptly compared to the Mississippi Scheme of Law in France and the South Sea Bubble in England, and not without good reason. They were all to be short cuts to untold riches, but in Holland, as elsewhere,

Humpty Dumpty sat on a wall,
Humpty Dumpty had a great fall,

and it took all the king's horses and all the king's men to put things anything like right again.

It must be remembered that the Tulip cannot have been a very common flower in Western and Central Europe in the early years of the seventeenth century. The first Tulip flowered in Holland in 1571, and in France in 1611. I mention these dates because it has been suggested, with great probability, that the fashion in Paris of ladies of the upper classes wearing costly flowers in their dresses and the rivalry of the young beaux to present the most expensive kinds was one of the

great contributory causes of the mania. For even then Holland specialised in bulbs, and the rarest and most beautiful Tulips in Western Europe were to be found there. Paris must have them at any cost. The fashion, too, was a long-lived one, and hence there was a long-continued demand.

This, coupled with the wish of the rich Dutch connoisseurs to obtain the best varieties for their own collections, gradually raised prices and kept them at a higher and higher level, until at length the idea got hold of everyone that growing and selling Tulips was a sure and easy road to riches. It is impossible to say how long the mania-time *par excellence* was in gathering. The year 1634 saw it firmly established, and from this time onward until just before the crash came in April, 1637, the chronicler has but to record one development after another, as the fever to get quickly rich spread

van der Eyck. We know this, because in Mr. E. H. Krelage's unique library of mania pictures and literature at Haarlem there are paintings of the most famous of these flowers, and one and all are broken or striped.

Now it by no means follows that two bulbs of the self-same variety will break alike—one may give good and the other poor variegations—nor does it follow that what was good this year will be ditto the next. Thus breeders, or plain, unbroken Tulips, were in much demand, and it was also an easy matter to sell inferior bulbs to what they were represented, owing to the difficulty of detection.

The other point to which I would draw attention as of particular interest is the wonderful bargains that were from time to time made for the acquisition of valuable bulbs. Of these we have documentary evidence, and they are unlike the herring and the

SAXIFRAGA MUSCOIDES AND THE COBWEB HOUSELEEK IN THEIR NATIVE HAUNTS.

among every class. Thanks to two Dutch works—the "t Samenspraecken tusschen Waermond and Gaergoedt" (or Conversations between Waermond and Gaergoedt) and the "Beschrijven der Kruyden" of Abr. Munting—backed up by recent researches by Sautyn-Kluyt and Solms-Laubach, we can get a good general idea of how the sales were conducted and the gradual evolution of necessary "conditions" to suit the altering circumstances of the time.

Before I try to describe these in some detail, I would like to make one or two general observations in order to elucidate what will be said hereafter. First, everyone may not know that garden Tulips begin life with a coat of only one colour, and that it is only after a certain lapse of time they become striped or, as it is technically called, "broken" or "rectified." It was only in this altered state that Tulips brought such very high prices as £280 for an Admiral

onion, the inquisitive botanist visitor, or the jealous connoisseur tales, inasmuch as they are true. I conclude this part of my article with a list of what was once given for a bulb of Viceroy, a celebrated byblœmen variety :

| | <i>Value in Florins.</i> |
|---|--------------------------|
| Two loads of wheat | 448 |
| Four loads of rye | 558 |
| Four fat oxen | 480 |
| Eight fat pigs | 240 |
| Twelve fat sheep | 120 |
| Two hogsheads of wine | 70 |
| Four barrels of eight-florin beer | 32 |
| Two barrels of butter | 192 |
| One thousand pounds of cheese | 120 |
| A complete bed | 100 |
| A suit of clothes | 80 |
| A silver beaker | 60 |
| Total | 2,500 |

Taking the florin at 1s. 6d., this gives the price of this one bulb as somewhere about £210.

JOSEPH JACOB.

(To be continued.)

COLOURED PLATE.

PLATE 1460.

NEW BORDER CARNATION W. A. WATTS.

THIS new Carnation is of the border type, the true garden Carnation, a plant that will grow well in any ordinary soil with simple care and attention. It has an excellent habit, with firm, erect flower-stems, non-bursting calyx and large, beautifully-formed blooms of just that delightful shade of deep rose pink called Rose Nilsson in the "Répertoire de Couleurs," page 120, a colour that pleases everyone, and can be used with telling effect in bouquets and in table decoration, besides being so charming in the border. Another attribute of this novelty is its fragrance, too often wanting in the modern Carnation. Mr. Watts, the raiser of this variety, has for many years

A BEAUTIFUL HYBRID ORCHID: BRASSO-CATTLEYA QUEEN ALEXANDRA DELL VARIETY.

worked among the Carnations, and has secured four certificates for new varieties. He has always protested against "dressing" the blooms for show, and has in the strongest terms condemned this practice and the paper collars, which, we are glad to say, are now much less in evidence than they used to be.

A USEFUL HARDY BAMBOO.

BAMBUSA PALMATA is one of the most ornamental of the Bamboos, and also one of the hardiest. It is remarkably beautiful with its broad, shining leaves, and, as it soon forms a large plant, it is one of the best where a handsome group is wanted for planting in the garden or in open spaces in the woods. *B. palmata* spreads rapidly in some moist places, where it grows taller than in dry soil. In the latter it does not always look happy, but a position prepared for it by deep digging and the addition of some good old manure will soon show how this Bamboo appreciates such treatment.

S. A.

THE GREENHOUSE.**NOTES ON CHRYSANTHEMUMS.**

THE BEST NEW VARIETIES TO GROW.

EVERY year new varieties are introduced. Some are of very high merit, others not so good. It is well, however, that all be grown by those cultivators who have time and space for the purpose. Amateur cultivators who have not the necessary space for the plants should only grow varieties that have been proved by experts to be the best. Furthermore, they should not discard older, tried sorts for those that are not proved to be, as yet, superior. It is good policy to rely chiefly on the established varieties, and to add approved new ones to them as occasion and necessity may arise. The following are really splendid new sorts, introduced during the

Fred Green.—A rich purple-coloured variety, with splendid leaves, dwarf habit. The plants should be propagated early, and stopped early in April in order to secure first-crown buds.

William Turner.—This is a grand white Japanese incurved variety which all amateurs should possess. The plants are easy to grow, and bear huge, well-formed blooms. Late first or second crowns are the best.

Mrs. Gilbert Drabble.—A marble white variety. The cuttings must be rooted early so as to obtain an early natural break and first-crown buds early in August. So treated, every bud will develop into a fine flower. It is a superior variety to Mrs. A. T. Miller, the petals incurving similarly, but being of better substance.

Lady Francis Ryder.—This is a pure white variety; the habit of the plant is good, the blooms are large, the petals reflexing and falling gracefully like a shower.

H. E. Converse.—Reddish bronze, with gold reverse, a very fine Japanese incurved variety. Propagate early, and take first-crown buds early in August. It is a very full-petalled variety, and develops into a deep bloom.

Harry Wood.—Crimson, shaded scarlet, long, reflexing petals.

INCURVED VARIETIES.

Doris.—A pure white, perfectly incurving.

Durbar.—A rich plum colour, with lighter reverse, finely incurving.

Heston Gladstone.—A white sport from the variety Lady Isabel. One of great merit.

Ethel Thorpe.—Silvery pink, high centre, a splendidly-formed flower.

Maritana.—Pure yellow, very large.

Master C. Hall.—Amaranth in colour, a large, refined flower.

SINGLE-FLOWERED VARIETIES.

Emily Smith.—A bronzy yellow, lovely in sprays, flowers late in the year.

Josephine.—Golden yellow, fine when disbudded.

Marjorie Lloyd.—A deep apricot, a large flower on stiff stems.

Margaret Gray.—A light bronze in colour, a beautifully-formed flower.

Mrs. Garner.—This is an improved Bronze Pagram, with gold tips and base; fine for exhibition.

Phyllis Bryant.—Sulphur yellow, a large, perfect flower. Avon.

A NEW BRASSO-CATTLEYA.

The most attractive feature of the Orchid flowers illustrated on this page is seen in the large expansive lip, which is deeply and most delicately fringed. The lip is certainly most beautiful in *Brassavola digbyana* and its many hybrids, and the variety illustrated was raised by crossing this species with *Cattleya Mossiæ* Wagneri. This hybrid, known as *Brasso-Cattleya Queen Alexandra The Dell* variety, is of clear ivory white colour, except for a shade of pale green in the throat of its exquisite lip. It was shown a few weeks ago by Baron Bruno Schröder, when it received the high award of a first-class certificate from the Royal Horticultural Society. It is a bold, massive flower, and one of the most handsome yet raised.

past two or three years, cuttings of which may be purchased at a very reasonable price:

His Majesty.—A rich crimson, with long, wide petals, which reflex evenly. It is an improved Master David.

King George.—Mulberry red in colour, long florets, a large bloom.

G. J. Bier.—Pure white, similar in form to the variety Hon. Mrs. Lopes.

Japan.—A deep orange yellow, broad, drooping petals.

Miss A. E. Roope.—Rich golden yellow, long petals, incurving at the tips.

Bob Pulling.—A very deep yellow, a large bloom with reflexing petals. This is a sport from Hon. Mrs. Lopes.

Francis Rowe.—Bronzy red on a yellow ground, with reflexing petals.

A. M. Thorpe.—Creamy white, a very deep bloom.

NEW BORDER CARNATION :
"W. A. Watts."

GARDENING FOR BEGINNERS.

HOW TO GROW MUSHROOMS.

MANY people would like to grow Mushrooms in their gardens. Many make the attempt—some succeed, others fail—but a great many do not make a trial because they think it is quite necessary to have specially-constructed houses in which to grow them. This is a mistaken idea. If there are cellars or sheds on the premises, Mushrooms can be grown in them when the necessary heating material is procured. Mushrooms may be grown in pure leaves, or in ordinary hot-beds in the open air; but as rather more skill is necessary than in growing them in sheds, I will confine these notes to the latter.

The Needful Essentials.—Materials that will combine to make a hot-bed which will be sweet and produce a medium lasting heat. Moisture of atmosphere as well as heat, consistent moisture of the bed without excessive watering of the latter being necessary. A darkened interior of structure, exclusion of all cold draughts, and fine regulation of all ventilation.

The Material for the Beds.—This is best when procured fresh from the stables; and newly-gathered tree leaves from heaps where fermentation has not set in. The horse-manure, and the short, strawy litter with it, must be gathered fresh every morning and spread out thinly in an open shed to partially dry, and be turned over every morning to allow the rank gases to escape. When sufficient has been gathered to form a bed, we will say one measuring 8 feet long, 4 feet wide and 14 inches deep, the whole must be thrown up into a heap and left so for one day and a night. A strong heat will be induced, but, before the material burns, the heap must be spread out again, when much rank steam will escape, and the manure will be thus sweetened and made ready for use in the building of the Mushroom-bed. This manipulation

2.—A RIDGE-SHAPED BED AND MUSHROOMS IN VARIOUS STAGES OF DEVELOPMENT.

of the manure is absolutely necessary if Mushrooms are to be grown successfully. When neglected, the spawn perishes and all labour is in vain.

Building the Bed.—On the space selected shake out a thin layer of the manure and some leaves—one-third of leaves to two-thirds of manure—and tread all down firmly. Build up the bed in layers in this way, firming each layer as put down. The firmer the bed, the longer will the heat in it last and the more even will it be. Insert a thermometer; the heat may rise to more than 100°. If so, wait until it drops to 85°; then insert the spawn.

The Illustrations.—Fig. A shows at No. 1 a brick of Mushroom spawn; at No. 2, the white

mycelium threads in it. The moist heat induces these threads to spread, and then Mushrooms grow from them. Nos. 3, 3 show the brick broken up into twelve pieces, which must be inserted 2 inches below the surface of the manure. No. 4, the retaining board of the bed, No. 5. The crosses denote the positions of the pieces of spawn put in 9 inches apart each way. Then cover the bed with new sifted loam 2 inches thick, make it firm, and finally cover all with a clean thatch of straw or hay from which the seeds have been beaten. No. 6 shows a section of the bed; No. 7, lumps of spawn; No. 8, soil and covering of straw. Where a shed is wide enough, beds on both sides may be made, as depicted at No. 9, with path (No. 10) between. A ridge-shaped bed is shown at No. 1 in Fig. B. No. 2, the bed; No. 3, spawn; No. 4, layer of manure and sifted soil on the lumps of spawn; No. 5, covering of straw.

How to Gather Mushrooms.—Do not cut them off as shown at No. 6, else the stumps will decay as shown at No. 7 and kill the mycelium near. Carefully pull up the Mushrooms as depicted at No. 8. The white threads are thus broken, and in and around the hole made as shown at No. 9 young Mushrooms will again grow. When gathered, cut off the stem and discard the stump, No. 10. No. 11 illustrates the young Mushrooms growing in the holes made by pulling. No. 12 shows a specimen that has grown to perfection, and must be used before it opens out any more. When carefully pulled, the tiny ones near will not be harmed, and will soon attain to a usable size. A good bed should begin to bear in six weeks from the time of spawning, and continue in bearing at least nine weeks.

Insect Pests.—Woodlice, without doubt, are the most troublesome pests to deal with. They must be trapped by placing sliced Potatoes about their haunts, or old pieces of wood under which they shelter. Slugs are likewise troublesome, and may be kept at bay by means of soot and lime or trapped on Lettuce leaves. G. G.

1.—SHOWING THE METHOD OF SPAWNING A MUSHROOM BED.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Hardy Ferns.—The growth on many having become unsightly, it will be advisable to cut it away and take advantage during open weather of cleaning the ground and top-dressing with well-decayed manure and leaf-mould. Any replanting where Ferns have become too crowded may now be carried out, well mulching any that are none too hardy after doing so. There are many places where the common Bracken might be introduced with good effect, not in the flower garden, of course, but on the outskirts, where the Ivies, St. John's Wort and Periwinkles are used to cover banks and old tree stumps.

Epimediums.—These delightful spring-flowering herbaceous plants delight in shady places. Here we have a collection planted with a few of the lesser-growing hardy Ferns, and the flowers brighten up the bed before too much growth is made. For the rock garden as well they should be planted, and when established are most effective.

The Rock Garden.

Alterations.—The weather has been of great assistance in carrying out the work of remodelling and replanting, and the planting of all the large material and shrubs will enable these to become well established by the spring.

Rock Plants in Frames.—Providing the plants in the pots are well plunged in ashes or sand or other suitable material, they will suffer but little harm from the weather. They should at all times be protected from heavy rains, but receive abundance of air except during severe frost, when the lights are best covered.

Hardy Primulas.—Owing to the mddness of the weather, several of these are beginning to throw up their spikes of bloom. The present is a suitable time to give the plants a good mulching of rotted manure—that is, when there is no frost in the ground.

The Rose Garden.

Planting.—It is advisable to get necessary planting completed without delay, and this relates to all sections. Where space permits and a Rose garden proper of formal beds is planted, the use of one variety to a bed has much to recommend it, and suitable varieties of free and continuous blooming kinds should be employed.

Climbing Roses.—The supports, whatever they may be, should at this season of the year be examined, and any that show signs of deterioration should be renovated. Wooden pergolas are very effective, but unless firmly constructed soon become dilapidated. The chief supports ought to be firmly embedded in the ground, and if the ends are charred, so much the better. An effective arrangement is obtained by placing three poles triangularly, and sloping to each other at the top. These ought not to be trimmed too hard, but have the side branches left several inches long. Here we employ them similarly in the shrubberies, and with splendid effect. Several of the conifers, such as *Thuyas* and *Thujopsis dolabrata*, when too large for removal, may be trimmed up and, the ground at the base having been prepared, make excellent supports.

Plants Under Glass.

Freesia refracta alba.—The growths of the various batches of these should receive attention in the way of support, and the easiest means of accomplishing this is to place three or four neat sticks round the edge of the pot and loop them up with a strand of twisted raffia or green tape. Keep the plants in a light position in a warm greenhouse, and now that growth is free, give sufficient water and occasional doses of liquid manure.

Coleus thyrsoideus.—As a winter-blooming plant there are few blue flowers to excel this, and for decorative purposes it is superb, as nice plants may be had in quite small pots, providing the plants are well fed at the roots. Over a ground-work of Maidenhair Ferns their arrangement is most effective.

Streptocarpus.—For blooming in the winter months, seedling plants in small pots are invaluable; it is one of the most useful subjects for indoor decoration. For this purpose the seed should be sown as soon as ripe, when it quickly germinates, and if

the seedlings are potted off and grown on in a warm structure, they soon develop into nice little material.

Fruits Under Glass.

Strawberries.—Unless exceptionally early supplies of fruits are required, the New Year will be quite soon enough to introduce plants in pots for forcing; then looking out the most promising crowns and putting them on a shelf in a light, airy structure for a time before placing them in a warm house.

Successional Houses.—As the Grapes are cut from these, the work of painting and generally cleansing should be proceeded with, so that the majority of the Vines at least are finished and ready for forcing again by the end of the year.

Bottling Grapes.—Place these in a cool, dark place, such as the fruit-rooms, where an even temperature is maintained, and cut sufficient of the wood so that the stalk is able to reach the water. Either end, however, will absorb the moisture to keep the bunch fresh. The bunches must every now and again be examined, and any bad berries cut out with the Grape scissors.

The Hardy Fruit Garden.

Bush Fruits.—Black Currants ought to be carefully watched for the mite or big-bud, which is readily detected, and if the bushes are old, grub them up and burn them. At the same time give the ground a dressing of lime, and then trench or dig and plant elsewhere. Purchase from a reliable source, selecting a good variety, such as Boskoop Giant. Black Currants, unlike White or Red, require but little pruning except thinning out the growths when these become crowded and generally keeping the bush shapely and in bounds.

Gooseberries.—The pruning of these is best delayed till as late as possible, or perhaps the birds will take the few remaining buds that are left on the spurs unless rendered distasteful; but this has to be done repeatedly, and by the former mode of leaving it, a crop, unless ruined by frost, is generally assured. The best varieties are so delicious as dessert fruits that oftentimes they are grown on trellises and walls, where they may be securely netted. A fence, either of wooden posts or iron, is cheaply constructed, and cordons planted in an oblique manner will produce fine fruits suitable for dessert or exhibition. Single, double or treble cordons, if grown against north walls, will be found exceptionally valuable, and take up but little space.

F. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Walks.—There has been a more than usual number of weeds (annual grass) on all the walks, and the only satisfactory way of cleaning at this time is to pick them by hand. It seems a big undertaking, but really it is not so. Wet portions where moss is growing are best freshened by turning the upper layer of gravel upside down.

Lawns.—A very slight application of sifted material from the compost heap spread regularly over the surfaces of lawns exerts a wonderful influence for good. Some lawns do not require it, but there are others, imperfectly prepared at first, to which such a dressing is all-important, but, judging from their appearance, always denied.

Worms.—Only once have I been troubled with the evil of a lawn morning after morning being rendered unsightly by worm-casts. The whole of the lawn was then watered with liquid impregnated with quicklime, to the final destruction of the worms. There are vermicides to be had for sprinkling over the surfaces and watering in, and certainly in bad cases either these or quicklime should be tried. Mild weather and before severe frost sets in are the best times to apply them.

Lily of the Valley.—Either now or early in spring the beds, after being thoroughly cleaned, should have about half an inch of material rich in fertilising matter applied smoothly all over the surface. New plantations may be made at this time, and it is worth remembering that this plant soon overruns even the space of 4 inches to 12 inches that may be allotted to small clumps. It is very soil-exhausting, so that as soon as the

spikes and the foliage begin to diminish in size after proper surface applications, a new plantation should be formed forthwith.

The Plant-Houses.

Palms.—There is no better time of year than the present for cleaning. The washing of large plants thoroughly requires more labour than it is possible in the majority of establishments to afford, but a solution of soft soap, petroleum and hot water at 180° both cleanses the plants and destroys insects, though one or even two washings must not be considered enough.

Cyaniding.—No more effective insecticide than the fumes of hydrocyanic acid is available, and where the gardener himself can, or is anxious to, operate so that he is sure no one can possibly come to harm by using it, I would recommend its employment in serious insect infestments. By allowing a lengthened period of the vapour in the house, a small quantity of cyanide of potassium is found to be as fatal to insect-life as a larger amount for a short period, without the risk of damage to vegetation.

Carnations.—The next six weeks are the most trying of any period to winter-flowering varieties. In the North at least it is no use trying to force the plants as some do. A little heat in the pipes to produce a buoyant atmosphere is essential, but as much fresh air as circumstances will permit should be allowed.

Young Plants.—All that can be expected of these is that they will extend their rooting system, and it may be noted that more roots are formed by keeping the soil only moderately moist than at any time wet, and their tops are strengthened. Usually no stopping need be done till January, when the lower buds will be well formed. Whether to shift on the more advanced plants from 2½-inch pots is one of those questions that must be decided on the merits of the case; but rather than risk a check by repotting it might be well to consider if a little manurial aid would not be sufficient to carry them on till the turn of the year. Malmansons should be kept in a perfectly quiescent condition. They are building up a strong system, though apparently inactive.

The Kitchen Garden.

Tomatoes.—A small sowing may be made now, to be followed by another a fortnight hence for producing plants to succeed those now well forward in pots. The seeds should be barely covered, and the covering of the lightest material. In a very high, moist temperature germination soon takes place, and without a high temperature at this period there is little use in trying to raise the plants.

Late Plants.—To ripen fruits properly, not less than 55° to 60° of heat should now be given. As a rule, when planted out, no water either at the root or in the house should be applied. It is a very curious problem why, but for years I have found that fruit can be produced for a very long period in the winter season under these conditions, and the more heat the plants receive, the better flavoured and coloured is the fruit.

The Hardy Fruit Garden.

Young Trees.—The early treatment of young fruit trees is not so well understood in these days as it was in the past. One thing is certain, that whether the tree is a bush or a trained wall tree, hard pruning is essential to obtain a "foundation." So essential is it that I never hesitate to cut back a badly-grown young tree so as to form a new start for it. With a good root system it soon makes up for the check.

With a Difference.—Apricots and Peaches, however, have a knack, if at all decently furnished, of overcoming the deficiencies in this respect of early years; therefore it is not necessary to take such drastic measures with these. Another thing of great importance to all kinds of young wall trees is to allow plenty of space for the shoots from the very beginning. It may seem advancing rapidly to have a shoot at every 2 inches or so, but that is a delusion and an assured method of weakening the tree which nothing else but thinning will stop.

Spraying.—I do not think the present is the best time to spray, but in the case of old trees covered with moss, a good drenching with a caustic solution should be given at any time, so that the parasite may be quite killed and cleared off before spring.

R. P. BROMBERGTON,

Tynninghame, Prestonkirk, N.B.

NURSERY NOTES.

MESSRS. DANIELS BROTHERS, LIMITED, NORWICH.

FOR a great many years the name of Messrs. Daniels Brothers of Norwich has been a well-known and highly-respected one in horticultural circles. As purveyors of high-class garden and farm seeds they are renowned the world over, and many good specialties, such as Daniels' Defiance Cabbage and Duke of York Potato, have emanated from their establishment. Although so well known in connection with vegetable and flower seeds, we do not think it is generally realised what an enormous nursery business they have; nor, indeed, were we aware of the extent of this side of their enterprise until we visited their nurseries at Norwich in the early autumn of this year.

These nurseries cover an area of about sixty acres, a greater part of which is devoted to fruit trees and Roses. The demand for these during recent years has been so large that Messrs. Daniels have had to take for nursery purposes land that was at one time devoted to root crops, and the effect of this new soil on the young trees has been truly remarkable. We have never seen a better stock of young Apple and Pear trees. All were the picture of health and cleanliness, and as they are growing on comparatively light soil, they should transplant well and give a good account of themselves in their permanent situations. A local Apple named Vicar of Beighton has a good reputation in the Eastern Counties, and is one that Messrs. Daniels first sent out. It is a rather large, solid Apple of dark red colour, and will keep well into June of the following year, when it is excellent as a dessert fruit. The Roses, too, were in splendid condition, all the best varieties being grown in abundance in both standard and bush form, as well as a large quantity of all the best rambler sorts in pots.

Strawberry plants are also a speciality of the firm, and at the time of our visit there were something like one hundred thousand sturdy runners ready for sale. Black Currant Boskoop Giant and the Red Fay's Prolific occupied a large quarter in one part of the nursery, and the nursery manager pointed out with pride the sturdiness and cleanliness of the whole lot.

In the hardy tree and shrub department we were particularly interested in some large quarters of the true cricket bat Willow, for which there is such a demand just now. To ensure propagating the right variety, Messrs. Daniels, several years ago, consulted the authorities at Kew, and secured the true variety of *Salix alba cærulea* grown from cuttings taken by Mr. Shaw, the eminent cricket bat maker, from a tree which he selected as being the best variety for making high-class cricket bats. The greatest care has since been exercised to keep the stock perfectly true. We also noticed a large number of young Clematises, all of which are propagated and raised at the nurseries. They were a particularly healthy lot that ought to do well in almost any situation when planted out.

In the hardy plant department Michaelmas Daisies in all the best and newest varieties, including the beautiful Climax, the double blue-flowered Beauty of Colwall and a charming large white-flowered variety named Snowdon, were growing in great profusion, as well as Rudbeckias, perennial Sunflowers, the beautiful *Scabiosa caucasica*, Heleniums, Kniphofias and a fine lot of Dahlias,

among these being a delightful bright rose pink decorative variety named Delice.

Passing reference has already been made to the enormous seed business that is done by the firm in their extensive premises in the Royal Arcade, situated in the heart of the city. Here seeds are sent to all parts of the world, the firm having a very large export trade. At the time of our visit bulbs of all kinds were being despatched, and it was interesting to note that all were of exceptionally good quality. We were privileged to see the first catalogue issued by the firm in 1871, this being a small booklet of comparatively few pages. Now two distinct catalogues, both running into hundreds of pages and both being of great artistic merit, are published, indicating in a concrete manner the enormous strides that horticulture and, incidentally, Messrs. Daniels' business have made since that time.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

"TINGITANA LILIES" (The Hon. Mrs. W.).—If by "Tingitana Lilies" reference is made to the Tanzier Iris (*I. tingitana*), a light protection of Larch branches, or these with Braeken Fern, would be desirable. We take it that only the growth is now showing, not the flowering spikes. The former is always made in autumn, and in our own case is about six inches high at the time of writing. In the case of freshly-imported bulbs from Italy, an earlier growth would be made, the danger being the breaking down of the shoots by snow later on. We presume the bulbs are fairly deep in the soil, 5 inches at least; if not, a mulching of Cocoa-nut fibre, 3 inches deep, should be given on the surface.

SWEET PEAS (M. C. L.).—As you only require the Peas for ordinary decorative work, it is quite possible that the border will serve your purpose for the third time. We cannot advise you, however, to give up the farmyard manure entirely. For the moment, however, you need not employ any. Instead of manure, give a dressing of lime, tipping a bush in a heap to each rod of ground, covering it lightly with soil to slake, and distributing it over the surface when finely broken down. Then you might deeply trench the whole, roughly ridging it after the manner of earthing up Celery. This will both aerate and drain the soil, while exposing it to the beneficial influences of frost. In February re-trench the soil, and manure it at the same time with well-decayed stable manure. Failing this, use Wakeley's Hop Manure, which is a good substitute, and again a short time before planting. The addition of sand or grit would be very helpful.

DELPHINIUMS AND OTHER PLANTS (E. L. M.).—We have never heard of a 6-feet-high red or crimson flowered Delphinium, and the raiser of such a plant would be considered fairly lucky. Of tall-growing sorts of other colours there are not a few, though not infrequently some of the tallest of all are weed-growing seedlings. The following are among the best: Barlowii vesicolor (rich violet), Diamdeur (rich cornflower blue, 6 feet), Dragonfly (violet, 7 feet), Félicité (6 feet to 7 feet, sky blue), King of Delphiniums (semi-double, gentian blue, 6 feet), Lizzie (Cambridge blue), Mme. V. Geslin (5 feet to 6 feet), Mammoth (sky blue and very tall), Princess May (sky blue and mauve, 7 feet to 8 feet) and St. Paul (rich azure blue, 7 feet). It should be stated that these heights represent the plants when established and well cultivated in good soil. The best tall perennials of the height named having reddish or crimson flowers are *Helenium autumnale* and *Kniphofia Uvaria nobilis*, *K. U. glaucescens* and *K. U. grandiflora*. *Lobelia cardinalis* Firefly and *L. c. Queen Victoria* are both superb in colour and admirable for grouping.

LOBELIA (W. T.).—The treatment recommended by our correspondent Mr. E. H. Jenkins is applicable to all forms of bedding Lobelia, and is much to be preferred to lifting and potting the old clumps, so many of which perish as a result of this check, and by reason of an exhausted vitality after a long period of flowering. The system is also equally applicable to such well-known bedding plants as *Alternanthera*, *Ageratum*, *Verbena* and other soft-wooded plants, which do not lift and transplant well when old. Apart from its value in this direction, the system is also a good economiser of space, a not unimportant matter for the amateur during the winter season.

TREATMENT OF PASSION FLOWER (W. S.).—Now that your Passion Flower has ceased to blossom, remove the ends of the branches to reduce the weight and keep it from being torn by wind in winter. In February, nail any shoots into position which may be required for extending the area covered by the plant; then cut the remaining side shoots back to within three eyes of the point where they join the main branches. Should any insect pests be noticed on the wood at that time, clean the plant with paraffin emulsion. Scale and mealy bug often attack the plant, whether it is grown indoors or outside. A dressing of well-rotted manure about the roots will do good if applied in spring.

HERBACEOUS PHLOXES (E. B.).—The following should meet your requirements. All are hardy and free flowering: Etna (deep red), Flambeau (orange scarlet), G. A. Ströhlein (scarlet), Boule de Feu (bright red), Elizabeth Campbell (salmon pink), Lindfield Beauty (salmon pink, with lighter centre), America (rosy centre), Jules Cambon (rosy pink), Selma (cherry red), Aquillon (glowing crimson), King Edward VII. (rich crimson), Evènement (rose pink) and Emile Littre (intense crimson). If to the above you would like to add other shades of colour, the following are all distinct and good: Mrs. E. H. Jenkins (snow white), Frau Ant. Buchner (grand white), Iris (deep heliotrope), Le Mahdi (violet), Eugène Danzanvilliers (lilac mauve, white centre) and Queen Alexandra (pale blue and silvery grey).

TREATMENT OF HELIANTHEMUM (A. M. P.).—In an ordinary way, and assuming the plants are of considerable age and size, we should have preferred to prune them back at the end of July, after the main flowering. In your district (Cornwall) it may be done even now, though we should advise this in a general way. The best plan of all, when the plants are getting out of hand a bit, is to prune them in February or March, and make up your mind that you would get no flowers in the year of pruning. But you would be preparing the plants for another year's work by giving them a full season's growth ahead. Apart from these things, the pruning of such plants should be anticipated, and by yearly keeping them within bounds dispense with that harsher method of cutting back which time often renders necessary.

SELECTION OF HERBACEOUS PHLOXES (Una).—The variety of Phloxes to which you refer are out of date. The following are among the more recent introductions: Jules Verne (clear blue), Frau Ock Buchner (white and rosy lilac), Königshofer (orange scarlet), Emmanuel Arene (deep blue), America (salmon rose), Asgir (brilliant scarlet), Albert Vandal (violet blue), Jules Cambon (rosy pink) white eye, Widar (Parma Violet blue), Lindfield Beauty (salmon), Frau Ant. Buchner (pure white), Mrs. E. H. Jenkins (not a novelty, but one of the grandest of white-flowered Phloxes), Le Mahdi (dark violet blue), Iris (crimson purple), Monnet Sully (orange scarlet), Etna (crimson scarlet), Esperance (rosy mauve), Météore (bright rose pink), Selma (salmon pink) and Splendens (vermillion). These include some of the best in cultivation at present.

PHLOXES DISEASED (M.).—Two of the stems, from their appearance, would suggest the presence of stem celworm at an earlier date. We did not, however, find any in those submitted for our inspection. All the stems sent, however, give proof of being very old plants, and their inferior condition might be due to deterioration. Spring propagation would be the best means of improving the condition of the plants, and if you lift some of the old plants in February and place them in a frame, new growth will be encouraged and cuttings of the right stamp rendered available. In taking the cuttings, select only those from healthy plants, which in all probability will grow away cleanly and well. You should take care to give the young plants an entirely fresh position and a deeply-cultivated soil. If you can command the slight warmth of a greenhouse, the cuttings would root more quickly than in a cold frame. Only the fresh portions of the growing plants should be used as cuttings.

CARNATIONS FAILING (M. S. F.).—We do not understand your non-success with these flowers, and can only suggest that some local influence is at work which you fail to appreciate. Are you sure as to the immunity of the soil from wireworm, and, if so, have you examined the stems below ground to see that no other insect pest is attacking the plants? Then, again, in what proportion have you used the sea-sand, and was it fresh, or had it been long exposed to the weather? If the former, that might be a cause of failure. Your rather heavy loam, unless very retentive of moisture, should suit these plants fairly well. The plants are not likely to do well if placed near the edges, though at some distance therefrom they might flourish. As for the flowers lying on the rocks, that is a matter for individual taste. If the soil is good and of fair depth, the Carnations might succeed on the rock bank if this is not too steep. You say nothing about the style of plant you have been employing or the season of planting. Generally, from your letter we should attribute the failure to poorly-rooted plants and indifferent cultivation.

TREES AND SHRUBS.

DESTROYING A HOLLY TREE (*Desider. Brompton*).—You can kill your Holly tree by exposing the main roots, boring holes in them and filling the holes with salt; or you may bore several holes in the trunk and fill them with salt. The removal of the bark will kill the trunk but not the roots. When the branches are killed, cut them off to within 6 inches or 9 inches of the trunk, and plant your Roses to grow over the snags. You may grow your Roses over the Holly without cutting the branches off; but the dead branches and leaves will look ugly until the Roses are strong enough to hide them.

TO PRUNE ROCK ROSES (*Rockery*).—The correct time to prune Rock Roses is as soon as the flowers are over. You may cut them back fairly hard, say, to wood which is three years old. When the plants are very large and old, however, it is sometimes preferable to destroy them and commence again with young plants, which may be easily rooted from cuttings inserted in sandy soil in a close frame during summer. If you do a little pruning each year, it is possible to keep the plants within bounds for a considerable time without having to prune them back into old wood and make them look ugly. If you simply wish to reduce the size of your plants without giving a general pruning, that work may be done at once.

HARDY EUCALYPTI (*Suffolk*).—The hardest of the different species of Eucalyptus are *Gunnii*, *coccifera*, *corata* and *urnigera*, the first named being entitled to the premier position. If the choice is limited to the five kinds mentioned by you, we should select the first four, thus leaving out *iminalis*. The best time to sow the seed is in the spring. It should be sown under glass, and the young plants be potted singly when they are large enough to handle. Then the following spring, when the frosts are over, will be a good time to plant them in their permanent quarters. We think your idea of planting the young trees 8 feet apart, with sheltering rows of Tamarisk, a good one, and cannot see that it can be improved upon.

DWARF SHRUBS (*A. C.*).—We fear that you have set us an impossible task, for we do not know of any low-growing shrubs with blue glaucous foliage and lilac or yellow flowers. Although none of these fits in with your requirements, the following are worthy of consideration: Lavender with its restful greyish foliage and well-known flowers; *Caryopteris Mastacanthus*, which has hoary leaves and spikes of blue flowers towards the end of summer; and *Ceanothus*, which, if pruned hard back each spring, may be kept near the stipulated height, one of the best blue-flowered kinds being *Indigo*. The leaves, however, are green. *Halmidodendron argenteum* is a silky-leaved shrub with purplish pea-shaped flowers. *Cytisus nigricans*, with yellow flowers, is about the height needed, but the leaves are not glaucous.

FALSE ACACIAS GOING WRONG (*F. W. H.*).—As you say that your False Acacia is badly infested with a scale insect, it is probable that this is the reason why the leaves have turned yellow. If such is the case, you should spray your tree with a caustic wash as soon as the leaves have fallen. Such a wash may be prepared as follows: Dissolve 1 lb. of caustic soda (98 per cent.) in 4 gallons of water. Then dissolve a quarter of a pound of soft soap in 1 gallon of water. Into this mix 2½ pints of paraffin to form a creamy liquid. Then mix the caustic soda and paraffin emulsion together, and spray over the affected tree. Use the mixture as soon as the leaves fall, and again in spring just before the buds burst. About the beginning of May commence spraying the tree once every ten days until the middle of June with paraffin and soft soap, but without the caustic soda. This will kill any young insects which may hatch out. It is possible that the root or trunk injury may be responsible for the bad condition of the tree, or partly so, and if that is the case there is little hope for it. You may safely reduce the heads of your trees to a diameter of 3 feet. The work may be done any time before the middle of February.

ROSE GARDEN.

ROSE FLOWER OF FAIRFIELD (*T. Day*).—This Rose is known as the Perpetual Crimson Rambler, and is badly addicted to mildew. We think you would find *Grüss* an Teplitz a far more beautiful Rose.

ROSES FOR SOUTH-EAST WALL (*F. P.*).—To replace the Belle Lyonnaise we should recommend *Mme. Gerard*, Climbing K. A. Victoria or Climbing Papa Gontier. The border should be deepened, say, to 3 feet; and provide the Rose with some good, well-rotted manure as well as some basic slag to the lower soil. A nice fragrant climber would be Climbing Lady Ashtown, Ards Rover or Florence H. Vetch.

ROSES FOR SMALL ARCHES (*T. B. W.*).—As you require Roses of less vigour than the ramblers, you could not do better than plant the following: Light varieties—*Alister Stella Gray*, *Aimée Vibert*, *Trier*, *Lady Waterlow*, Climbing Lady Ashtown, *Johanna Sebus* and *William Allen Richardson*. Dark varieties—*Hugh Dickson*, *Grüss* an Teplitz, *Sarah Bernhardt*, *Zepherin Drouhin*, Climbing Liberty and Longworth Rambler.

ROSE FOLIAGE BLIGHTED (*J. R. D.*).—The foliage sent is infested with orange fungus. It appears late in the season and rarely does much harm, and you can do little now to stop it. Another year spray early and often with Bordeaux mixture. All fallen leaves should be burnt, and the surface soil about the plants removed in winter and also burnt. Only an inch or 2 inches of the surface need be removed, and this could be replaced by other good soil and manure.

ROSE DELIGHT (*H. E.*).—Yes; this is a very good variety, not so very distinct, however, from *Maiwatha*, and it is certainly not equal in value to *Alberic Barbier*, one of the loveliest of all wickurianaes. There is a great advantage in having wickurianaes Roses on their own roots, and we differ widely from Mr. Pearson as to *Lady Gay* not growing on its own roots. We have this Rose in this form growing most luxuriantly, and have not found one of the wickurianaes but what will succeed upon its own roots. Shower of Gold is a most beautiful variety, and will be largely planted when better known. Its delightful foliage alone recommends it. One may say the flowers are a shade or two deeper than *Alister Stella Gray*. It lacks the perpetual character of this latter Rose, although it makes up for this in its extraordinary vigour. We suggest planting both on one arch, the one to give continuous blossom, the other to quickly clothe the foremost part of the arch.

LAYING OUT A SMALL ROSE GARDEN (*M. S. W.*).—We think you would like parallelogram beds better than oblong ones to surround the circular bed in the centre. These parallelogram beds can be made any length, but their width should be about half the diameter of the circular bed. We would suggest the central bed of a good red rather than a white, and you would find *General Macarthur* a more tidy grower than *Grüss* an Teplitz. This latter is all very well in a large rosery, for its growth is so strong. It is, like *J. B. Clark* and *Hugh Dickson*, quite unsuitable for ordinary bedding. *Mme. Abel Chateaux* and *Caroline Testout* would be all right for pinks, although we should prefer *Mme. Leon Pain* to the latter, and for a yellow *Mme. Ravary* would do well, but we could not well recommend *Lyon Rose*. It is rather erratic. In some gardens it grows splendidly, and in others it is a failure. We would advise either *Duchess of Wellington* or *Artium B. Goodwin* as an opposite companion to *Mme. Ravary*.

THE GREENHOUSE.

MIGNONETTE (*A. C.*).—It is most essential that the Mignonette be given a good light position, and have plenty of air at all times. Failure to comply with these requirements is, no doubt, the cause of your non-success. In order to grow Mignonette well, the soil should consist mainly of good loam, with an admixture of broken brick rubble and sand. It should also be pressed down very firmly. In addition to this, the soil must not be kept too wet.

BLUE HYDRANGEA (*A. C.*).—It is a difficult matter to ensure blue flowers on the Hydrangea, though a fair measure of success is (if the soil is quite free from lime) obtained by watering the plants occasionally with alum water, at a strength of 1oz. to each gallon of water. Iron, too, is employed by some, the method followed being to mix about a tablespoonful of iron with each peck of soil, and in addition, as the pots get well furnished with roots, put a pinch in the water about once every week. If in the open ground, the plants can be watered with the mixture. Some nurserymen make a speciality of blue-flowered Hydrangeas, but the method employed is a trade secret.

LAPAGERIAS (*Suffolk*).—The cause of your Lapageria leaves turning brown and dropping off is that they are badly attacked by thrips, which are present in great numbers. We have invariably found that the XL All Vaporiser is perfectly effectual in destroying these pests; that is, perfect insects, though occasionally some of the eggs may escape. The remedy for this is to vaporise three or four times at intervals of about a week. Instead of this you may, if you wish, syringe with one of the many insecticides that are now to be obtained. Another point concerning your Lapagerias is that, judging by the leaves sent, we should say that the roots are not in a very satisfactory condition, and sickly plants are far more prone to the attacks of insects pests than healthy ones. If the condition of the roots is attended to, it will doubtless in the future do a good deal towards keeping these pests away.

SPORT FROM CHRYSANTHEMUM: J. C. GRIEVE (*R. B.*).—The blooms you were good enough to send us are absolutely identical with those of an old Continental introduction bearing the name of *Mme. Casimir-Perier*, the blooms of which have a creamy white centre, tinted pink, just like the flowers you sent to us. *Mme. Casimir-Perier* gave a sport of a beautiful yellow colour, shaded and striped red, and this sport bears the name of *Mrs. A. Willis*. The latter has frequently reverted to the original, and the original has often sported to the same colour. Your plants are therefore of no more than ordinary value. *J. C. Grieve*, the name of the plant from which your sport was derived, is unknown to us, and is not catalogued by any of our leading specialists, nor is it in the catalogue of the National Chrysanthemum Society. It is possible that it may be identical with *Mrs. A. Willis*, to which we have called attention, hence the reason of your possessing the sport that is none other than *Mme. Casimir-Perier*.

FRUIT GARDEN.

INJURY TO PEAR LEAVES (*F. W. R.*).—The Pear leaves have been badly infested with the Pear leaf-bliester mite, *Eriophyes Pyri*. These mites winter in the bud scales. In spring they enter the leaf and cause the formation of small galls. Eggs are laid within these, which soon hatch out to produce mites. These make other galls, and so the process goes on through June, July and August. As the galls grow older they change colour, ultimately becoming black. Infested leaves should be hand-picked as far as possible. Apply the lime, sulphur and soda wash twice—early December and February. Spraying must cease

in spring as soon as the bud scales are fully opened. Lime, sulphur and soda wash: Lime, 3lb.; sulphur, 3lb.; caustic soda, 1lb.; soft soap, 1lb.; water, 10 gallons; or quantities in proportion.

CREOSOTE AND GRAPES (*F. F. M.*).—It is well known that fruit does absorb the flavour of the material by which it is closely surrounded. A case in point is Apples or Pears packed in or stood on straw in the fruit-room. The straw becomes more or less damp by the moisture resulting from the sweating of the fruit, causing it to become musty and of unpleasant odour, which, as we know too well, is communicated to the fruit. But we were not before aware of the extreme sensitiveness of Grapes in this direction. How often it has happened in our experience that we have tasted Grapes in all other respects seemingly all right, and having a peculiar, foreign and disagreeable flavour. This is also often the case with Melons, and sometimes even in the case of Peaches. Does your experience with the creosote and your Grapes give a clue to the causes in so many other cases?

MISCELLANEOUS.

FUNGUS ON RUSTIC CHAIR (*F. S.*).—It is probable that the wood of your chair is full of mycelium, hence the repeated growth of the fruiting stage of the fungus. All that you can do is to soak the affected parts in a strong solution of carbolic acid or permanganate of potash. This may be done by applying the liquid repeatedly with a paint-brush. Should it not prove effective, remove the fungus-infested sections and make up with new wood.

POOR LAWN (*A. H.*).—You cannot do better than rake your lawn over with an iron-toothed rake to take out as much of the moss as possible; then give a surface-dressing, 1 inch or 2 inches deep, of rich soil. Apply the dressing early this autumn and keep the soil raked well about until it disappears. Where the grass is very thin, a little new seed may be sown next spring. Prick the thin places up with a fork, sow the seed, rake it in and roll lightly. About May a dressing of bone-meal may be given with advantage. Do not play on the lawn next year until the grass has filled up well.

FRENCH GARDENING (*Intensive*).—Instruction in practical intensive culture on the French market-garden system may be obtained at the Burhill French Garden, Walton-on-Thames; or at the French Garden, Shepperton, both large and well managed. The system may be practised in most parts of the kingdom, but preferably in localities where there is a clear, pure atmosphere and a good supply of light during the winter months. Most parts of England and Ireland are suitable, and also the South-West of Scotland. You will find full particulars of the system, with cultural instructions, in "French Market Gardening," published by John Murray, 3s. 6d. net.

ORIGIN OF MARGUERITE CARNATION (*W. T. S.*).—There appears to be a certain amount of doubt regarding the origin of the Marguerite Carnation; but, according to the late Mr. James Douglas in "Carnations and Pinks" of the "Present-Day Gardening Series," the writer was informed by Mr. Ernest Benary that some say it originated in Sicily, also that Messrs. Dammann and Co. and a Mr. Hildebrand both claim to be the first to have grown the plants. The members of this section are not hardy and perennial in the same sense as are border Carnations and Pinks. They are, as a rule, raised from seed sown early in March, and the young plants grown either in pots or planted out. In this latter case they are lifted about the end of August, so as to become established in pots before winter. They are chiefly employed for flowering at that season, and in a temperature of 55° will yield a quantity of blossoms.

FAIRY RINGS IN GRASS (*W. H. B.*).—By brushing up the small Toadstools, which appear about the fairy rings on your lawn, you are spreading the disease. The Toadstools are the fruiting stage of the fungus which causes the trouble, and by disturbing them in the way you describe, the spores are distributed about the lawn. A better plan would be to pick them off carefully and burn them. There are two ways of eradicating the fungus. One is to water the rings well with a strong solution of sulphate of iron. The other is to dig the soil out in the region affected to a depth of 12 inches and make up with new soil. As the mycelium of the fungus spreads in an outward direction, the soil should be removed to a distance of 3 inches or 4 inches beyond the outer part of the circle; but there is no reason to go beyond the inner part of the ring. The latter is the most efficacious method of dealing with the trouble, for when sulphate of iron is used, new turf has to be laid afterwards, and unless the ground is thoroughly soaked, some of the mycelium is almost certain to be left alive.

NAMES OF PLANTS.—*Fern Dole*.—One of the many hybrids of *Veronica speciosa*.—*C. S. S. J.*—*Salvia rutilans* (Pineapple-scented Sage). This was the only specimen enclosed.—*Rev. R. H. W.*—All three are evidently *Saxifraga* hybrids, which it is impossible to name in this condition. No. 1 and 3 appear to have some *S. longifolia* or *S. crustata* in them, while No. 2 may be a hybrid of *S. aizoon* and some other.

NAMES OF FRUIT.—*Holme*.—Apple Quern Caroline.—*J. T. S.*—Burondeau.—*J. T.*—Beurré Diel.—*An Old Subscriber*.—Apple Court Pendu Plat and Pear Swan's Egg.—*A. E. D.*—Bergamotte Esperen.—*A. R. T.*—18, Ribston Pippin; 19, Jolly Beggar; 20, Beurré Dumont; P. Aston Town; 9, Maréchal de la Cour; A, Wormsley Pippin; A3, Warner's King; A4, Alfriston; A5, Venus Pippin; A6, Royal Nonsuch; A8, Victoria; A9, Lamb Abbey Pearmain; A11, American Mother; A12, Bess Pool

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Dates of Shows for Next Year.—We shall be glad if the secretaries of horticultural societies who have not already done so will send us the dates of their shows for next year, so that they can be included in the almanack that we are presenting with our Special New Year Number.

The Potato Crop in England and Wales.—According to the preliminary statement just issued by the Board of Agriculture, the total production of Potatoes in England and Wales is estimated at nearly 2,244,000 tons, which represents, on an area of 463,000 acres, a yield of 4.85 tons per acre, the lowest since the returns of produce were first collected in 1884. The worst return previously was 4.97 tons per acre in 1907.

Primula obconica in Glasgow.—Among the finest plants of this Primula that we have recently seen are those in some of the Glasgow parks. Mr. Thompson, who has charge of the Springburn Park, under Mr. James Whitton, the Superintendent of the Glasgow Parks, has a specially fine strain, to which it is evident much care is devoted. One could hardly find a poor one among the plants, and they surpass, or at least are fully equal to, some noted strains which have won prizes at prominent Scottish exhibitions.

The Florida Water Hyacinth.—This is the popular name of the well-known stove aquatic Eichornea crassipes. This plant floats freely upon the surface of the water without the roots being anchored in the soil. In warm countries, where this plant has been introduced by virtue of its interest and beauty, it has increased at such an enormous rate as to impede water traffic and choke waterways. As a stove aquatic it is a plant of great beauty; its many flower-racemes in violet blue make it a charming subject for a warm Water Lily tank.

The Orange-berried Holly.—A correspondent sends us a Holly shoot laden with berries, which, instead of being of the typical yellow-fruited kind, are orange flushed with red. Plants bearing fruits of this character may often be noted in a batch raised from seeds of the yellow-berried Holly (Ilex Aquifolium fructu-juteo), while such a variety has been given the varietal name of fructu-aurantiaca and the popular name which heads this note. The yellow-berried plant has been known for several centuries, and old gardening books inform us that it was found wild in a wood near Wardour Castle in Wiltshire, and also at Wiston in Suffolk. A form with white berries has been described, but it is doubtful whether it is now in cultivation.

The Shrewsbury Show Secretaries.—The many supporters of the Shrewsbury Show will learn with regret of the resignation of the hon. secretaries, Messrs. Adnitt and Naunton, who have acted in that capacity since the Shropshire Horticultural Society was established thirty-eight years ago. The Shrewsbury Show is one of the largest of its kind in the country, and since it was first held the society has granted donations amounting to nearly fourteen thousand pounds to the Shrewsbury Corporation for the improvement of the show grounds, public buildings and institutions.

New Zealand Daffodils in London.—We understand that there is a possibility of all the best and newest Daffodils that have been raised in New Zealand, and some of which were commented upon by Mr. F. Herbert Chapman on page 598 of our issue for November 30, being grown in this country and exhibited in London. This will enable us to judge of their merits and to compare them with the latest productions of raisers in this country. We are not at liberty to divulge details of the proposed scheme at present, but, should it mature, it will be of considerable interest and value to Daffodil-lovers.

A Noble Tropical Plant.—For the last two months Brownea Crawfordii has been the centre of attraction in the Palm House at Kew, for it has carried a large number of inflorescences of bright scarlet flowers. The various species of Brownea are natives of Venezuela and Colombia, but several hybrids have been raised, and of these B. Crawfordii is not only one of the best, but one of the most beautiful members of the whole family. Forming a tree with a wide-spreading head, it produces long, pinnate leaves and terminal heads of flowers. It is only in a large house with a tropical temperature that the plant does itself justice.

Three Good Red Currants.—These useful fruits are extensively cultivated in both large and small gardens, but the best forms are not always selected. We have found that Raby Castle, La Versailles and La Constante are a trio of the best, and can be procured for a moderate outlay. The first may be described as a good one for general purposes; the second can be employed as a cordon, and if planted on a north wall or border the supply of Currants will be prolonged. The berries are large, and the bunches are produced in abundance. La Constante has no equal as a late variety, the big red bunches remaining in excellent condition for several weeks after other Currants are finished. Now is a good time to plant all small fruits. In town gardens sparrows often do much damage to Red Currant and Gooseberry bushes at this season by eating the buds, and where trouble of this kind is likely to occur some old fish netting should be spread over them.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Injury from Chrysanthemum Rust.—I should like to ask if any of your readers have felt any ill-effects from the Chrysanthemum rust? I and my foreman were arranging groups of standards in the conservatory, and the day following we were both swollen to an alarming degree on all exposed parts of the body. My medical adviser diagnosed it as uraturia, a mild form of blood-poisoning; and he thinks, too, that it was probably set up by the Chrysanthemum rust. No pain accompanied it, but severe irritation.—FRANK W. SARGEANT.

A Beautiful Berried Shrub.—We have in *Coriaria terminalis* a shrubby plant of some beauty and distinctness, owing its principal charms to its elegant growth, its autumn berries and the colouring of its autumnal leaves, the three combined rendering this *Coriaria* a plant of some attraction for places where it will fruit freely. In cold situations

ease with which *C. longiflorus* can be grown in the alpine garden may be realised when it is stated that the group shown in the accompanying illustration consisted, four years ago, of three small corms, which have remained untouched in their present position in very ordinary soil, consisting of heavy loam, road grit and a small quantity of leaf-mould; aspect, full south.—REGINALD A. MALBY.

Fragrance in Chrysanthemums.—I am much interested in the references to the single-flowered Chrysanthemum Eric Harvey in a "Note of the Week," issue October 26, and again on page 598, November 30. The variety in question is stated to be very fragrant, which is a step in the right direction. Probably the variety your correspondent C. Turner refers to is *Ladysmith*. The old hirsute variety, Mrs. Alpheus Hardy, was the sweetest-scented Chrysanthemum I ever grew. Another hirsute variety, *Louis Boehmer*, is also fragrant. Several other sorts, not now in cultivation, were very fragrant. The newer one, Mrs. G. Hemming, a large Japanese, is very fragrant,

with the added virtue of fragrance is sure to become popular. The flower, from the description in a "Note of the Week," October 26, *re* Eric Harvey, I should think is somewhat similar in colour, and in an early issue I shall hope to hear of others possessing this hitherto unknown virtue.—A. E. BRADY.

Cercidiphyllum japonicum in the United States.—The reference to *Cercidiphyllum japonicum* on page 574 of THE GARDEN for November 16 leads me to report that this species makes a first-rate tree in Massachusetts. We have a number of beautiful specimens growing in the College grounds, and there are others in the town. In "Bailey's Cyclopædia of Horticulture" this species is said sometimes to reach 100 feet in height; but this must be in Japan, for I feel sure there are no such specimens in America. It colours very nicely here in the autumn, but does not compare with the Japanese Maples nor with our native American Maples, nor, indeed, with many other of our American trees and shrubs.—F. A. WAUGH.

Snow and the Germination of Seeds.—The recent snowfall and the near approach of the seed-sowing time induces one to ask for the experience of others respecting the hastening of germination in certain seeds by a covering of snow, and to mention one or two things regarding this. It will be observed that in early spring, immediately after a fall of snow, many seedlings of hardy plants—perennial, biennial and annual—appear. In the case also of certain seeds sown in pots, pans or boxes, if they are covered with snow and this allowed to remain on for a few days before it melts, the germination of these seeds appears to be hastened. This is particularly the case with seeds which are slow or irregular in their germination, and it has long been the practice of certain raisers of Auriculas from seeds to take advantage of this when suitable weather occurs. I have tested this, and have found that the germination of Auriculas and other Primulas is really hastened by this covering of snow. It appears to me that this practice is specially useful with seeds which are usually very slow. The Gentians and some of the awned Anemones are instances. Perhaps others may add their quota of experience.—S. ARNOTT.

Dinner-table Decorations.—At all the principal haws throughout the country there are classes provided for dinner-table decorations. Where the flowers used are restricted to Carnations, Roses, Chrysanthemums, Narcissi and Tulips, with any kind of foliage, and a maximum height is given which must not be exceeded, the competitors are placed on a fairly equal footing. This is never more clearly defined than in the case of Sweet Pea tables. I hold that all competitors should be given as wide a range as possible in the matter of dinner-table decorations, but I think that committees and those who frame schedules should stipulate that spaces be left on the tables for the large plates at least. Often enough one sees the whole of the table covered—very charmingly, too, as regards the floral designs—but no space is left for plates. I do not intend going into the merits of high *versus* low decorations, on account of taking up too much valuable space, but would simply say that I favour low designs which are graceful and light and not necessarily squat in appearance, and plain glass vases for the flowers to be placed in. One large plate for each diner should be placed in position on the table, but no glasses, knives, forks, nor spoons. I am quite sure that inexperienced decorators would gain a clearer insight into the manner in which a table for diners should be furnished with flowers and foliage.—G. G.

CROCUS LONGIFLORUS, A BEAUTIFUL AUTUMN-FLOWERING SPECIES, IN THE ROCK GARDEN.

it seems hopeless to expect it to fruit; at least, the writer has tried it for seven years or so in succession in a cool, though not cold place without being favoured with any fruit. In warmer positions, however, it gives handsome, arching branches, bearing at their summit clusters of bright yellow, Currant-like fruits in August, while later the foliage dies off a good red.—S. A.

A Beautiful Autumn Crocus.—One of the brightest patches of colour in my garden at the middle of November was *Crocus longiflorus*. At the time of writing it was in its full glory of rosy lilac, and when a warm gleam of sunlight pierced the smoke-laden air, the rich orange stigmata gleamed within the lovely chalice rising from the dark soil, accompanied to about half their height by the grass-like foliage. While in general aspect the Crocus is not unlike *C. speciosus*, it is dwarfer and more refined, both in shape and colouring, while *C. speciosus* generally flowers about September and early October, and is, so far as I have grown it, unaccompanied by any foliage. The

and I have for many years noticed that the purple, violet and amaranth coloured varieties are more fragrant than any others. When the sun shines on the blooms is the time when their fragrance is most perceived, and more single-flowered varieties than those of any other section are sweet-scented.—G. GARNER.

— In response to your invitation in the note under "Fragrance in Chrysanthemums," November 30, I may say that early in the spring, having added single varieties to my small collection, one of these named Good Hope, a deep puce-rose coloured variety with a white zone circling a bold yellow disc, was most pleasantly fragrant. My friends said it was like Honey-suckle, only more "almondly." We first noticed the perfume indoors in blooms in a cut state with other flowers. It was so sweet and agreeable that we sought out what it could be, never dreaming it was the Chrysanthemum; we found it was, however. The flower, owing, I think, to the white zone, was most attractive, and always invited attention, and

How to Exterminate Moles.—Your correspondent H. C. Wood, page 598, issue November 30, gives some very useful hints on this subject. It may be interesting and useful to add that moles have their regular times for feeding, namely, at six o'clock and nine o'clock in the morning, again at noon, at three o'clock in the afternoon, and at six o'clock and at sunset. If one waits patiently about six yards away from the last-made hillock he may see the new one rising, and when it is nearly complete he should step up carefully and dig out the mole, treading down the newly-made run at the same time. Moles generally have their home in a dry bank, and from it make a main run or tunnel to the feeding-ground. The trap should be set in this main run.—B.

Teuerium fruticans.—Although this evergreen shrub is not hardy enough to stand uninjured through a winter of ordinary severity in the Midlands, it thrives excellently in Devonshire, Cornwall and South Wales in the open ground, while about London it gives very good results when planted against a wall. Belonging to the Sage family, it does not show any marked resemblance, except in the formation of its flowers and by its square branches, to any of the Salvias, for its woody shoots are long and slender and, when young, covered with a dense white felt. The ovate leaves are similarly covered on the under surface, and are greyish green above. The flowering season is a very prolonged one, for it extends from early summer until the approach of winter, the lavender or bluish flowers being borne from the leaf-axils near the points of the branches. No difficulty need be experienced in its cultivation, for, providing climatic conditions are favourable, it thrives in any good garden soil. Cuttings may be rooted with ease in sandy soil in a close frame during the summer.—D.

The Gargano Bellflower.—This is *Campanula garganica*, which should be represented in every garden in one or other of its forms. It is more suitable for the rockery than for the border, although it may be cultivated in the latter near the front, or, where there are rock edgings, over these. The different forms all make low, trailing plants of neat foliage, profusely covered for a long time in summer with pleasing open blue flowers. Trailing over the rocks and stones of the rockery they are exceedingly pleasing. *C. garganica* itself has charming glossy, neatly notched leaves and good blue flowers, and is a capital front-of-the-border or rockery subject. There is also a pretty white variety of this named *C. g. alba*. A favourite form is *C. g. hirsuta*, which has pleasing greyish, downy foliage and delightful open flowers of light blue with a white centre. It is probably the best of the Gargano Bellflowers. There is also a white variety of this called *C. g. hirsuta alba*. *C. garganica* and its varieties are easily grown in light soil, and flower more freely and last longer in partial shade than in sun.—S. A.

FORTHCOMING EVENTS.

December 16. — National Chrysanthemum Society's Executive Committee Meeting at Carr's Restaurant, Strand, at 7 p.m.

December 17.—Royal Horticultural Society's Committee Meeting (no exhibition).

December 19.—Linnean Society's Meeting.

December 30.—Hereford Fruit Show (two days).

January 7, 1913.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster, S.W.

GARDENING ACROSTICS.

AS outdoor work is necessarily more limited in winter than in the other seasons of the year, it has been suggested that some of our readers might like to take part in an acrostic competition as a useful and profitable substitute for their usual activities in other directions.

Accordingly we propose to publish, from December 14 to February 1 inclusive, a series of eight double acrostics, each of which will relate entirely to gardening or simple botany. As a slight incentive we offer three prizes, of the value of £3, £2 and £1 respectively, which, at the close of the competition, will be awarded to the successful competitors under the following conditions:

1. Solutions must be sent to the Editor at 20, Tavistock Street, Covent Garden, London, W.C., within a week of the date of issue in which the acrostic appears; thus, solutions for that in the paper of December 14 must be received on or before December 21.

2. Each solution must be accompanied by the sender's name and address, and, if it is thought desirable, a *nom de plume* for publication as well.

3. Envelopes must be plainly marked in the left-hand corner "Acrostic."

4. The correct solution of each acrostic will be published weekly in due course, together with a list of all those who have sent the right answers. N.B.—We then propose to give, where necessary, explanatory notes and references to the more difficult "lights" in order to make the acrostics as useful and instructive as possible.

5. In all cases the Editor's decision must be final.

6. If more than one competitor has sent in correct solutions to all the acrostics, the prize-money will be divided on the following lines: If two, the money for the first and second will be added together and then divided; if three or more, the whole of it will be added together and then divided equally among the successful competitors. The second and third prizes will be similarly dealt with, supposing similar circumstances should arise with regard to them.

7. The names of the prize-winners will be published in THE GARDEN of February 15, 1913.

EXAMPLE OF A DOUBLE ACROSTIC.

My first is found in my last, and with it makes my whole.

1. Contemporary with the Almond and the Vine, I have been an inhabitant of the fruit garden from time immemorial.
2. The Woodbine in a Latin dress.
3. I make baskets, and sometimes divining-rods.
4. An old-fashioned Cheshire name of the Plantain.
5. Green I am bitter and tough—white I am crisp and mild.
6. The Rose Bay.

SOLUTION: "FLOWER GARDEN."

EXPLANATORY NOTES.

* In "Johnson's History of English Gardening," pages 3, 16 and 17, it is mentioned as a garden

fruit in Jacob's time. † "Folkard's Plant Lore," page 113. Osiers are used as divining-rods by some Eastern nations. ‡ "English Plant Names," by Britten and Holland. Waybred (spelt in various ways) is a common local name for the Plantain, especially in Cheshire.

DOUBLE ACROSTIC No. 1.

My firsts: *The country of new plants.*

My finals: *The glory of an autumn border.*

My whole: *A much-developed annual. First made by Nature in the East, but now by man in the West.*

1. Famous in Miller's day for its garden, now for its show.
2. When I am a gay garden flower, I am an annual; but when I am eaten, I am a perennial.
3. I look a wee bit like a *Gladiolus*. I am, anyhow, much more beautiful than I was twenty-five years ago. The contents of my seed-pods suggest the name you seek.
4. The name a botanist gives to that part of a stem whence leaves spring.
5. I love the damp when living, and I can keep you from it when dead.

The solution to the above, with explanatory notes and the names of those who have sent correct solutions, will be published in our issue dated December 28.

CULTURAL HINTS ON NEW OR RARE PLANTS.

ALPINES.

Saxifraga apiculata alba.—This plant needs no recommendation beyond the fact that it is a valuable white sport from a plant which everybody admires. With all its attributes of vigour and free flowering typical of the original, it is destined for great popularity. Valuable alike for rock garden and alpine-house, it is a plant to grow. Easily increased by division.

Haberlea rhodopensis virginialis is considered one of the choicest of alpine gems for flowering in May and early June. The plant is a lover of cool rocks and a sequestered spot, and, while detesting much lime, delights in sandy peat and leaf-soil. Moisture, too, should be liberally supplied. In effect it is a miniature white-flowered *Streptocarpus*. Increased by division and seeds, when procreable.

Anemone nemorosa Allenii.—Those who know and prize the beautiful *Anemone robinsoniana* will be pleased to know that this is a far superior variety; one, moreover, that will luxuriate in rich, moist soils, and give a good account of itself when the time for flowering comes round. The plant is not a generous seeder, but may be divided when established. Plant now, burying the roots 4 inches deep.

Wahlenbergia vincaeflora.—Lovers of the choicest plants will welcome this elegant-looking subject with its never-ending array of gentian blue flowers on frail stems 15 inches or so high. The plant is in flower for weeks. I would suggest a protecting crevice for it in the rock garden, with a deep root-run of peaty or leafy loam. Seeds should be looked for as a good means of increase. It flowers from June onwards. Plant in spring.

(To be continued.)

TREES AND SHRUBS.

ORNAMENTAL BRAMBLES FOR WINTER EFFECT.

PLANT collectors in China during recent years have enriched our gardens by the introduction of many new trees and shrubs. Prominent among these are a considerable number of Rubi or Brambles. Mr. E. H. Wilson during his three expeditions collected seeds of fifty species and varieties. Exactly how many of these will

A NEW FORM OF THE WHITE-WASHED BRAMBLE (*RUBUS BIFLORUS QUINQUEFLORUS*).

find a permanent home in our gardens it is difficult to say at present, but at least ten or twelve species already give evidence of becoming popular.

The different species and varieties vary very much in growth, foliage and appearance generally. Several form large bushes with stout stems up to 12 feet or 15 feet in height; others produce long, slender, trailing shoots. Their principal value in gardens lies in the ornamental foliage and attractive stems. One or two of the better fruiting kinds, though in themselves not superior to our common Bramble, yet may prove of considerable value in the hands of the hybridist. The three most

noteworthy at present in this respect are *Rubus adenophorus*, *R. biflorus quinqueflorus* (see illustration), and *R. kuntzeanus*.

For Pillars and Pergolas their value and uses in the garden are considerable and varied. Those with long, slender, trailing shoots are suitable for pergolas, arches and pillars, particularly several of the evergreen species. The species with ornamental stems or attractive foliage are valuable for the shrubbery borders, beds in the pleasure grounds, or groups in open spaces in view of the woodland walks. When planting the white-barked Brambles, to get the best effect at least eight or ten plants should be grouped together. A selection with attractive stems in winter are *R. biflorus* and the variety *quinqueflorus*, *R. giraldianus* (see illustration), *R. lasiostylus*, *R. mesogæus* and *R. thibetanus* (*Veitchii*). Evergreen species suitable for clothing pergolas, arches, verandahs and pillars include *R. bambusarum*, *R. flagelliflorus*, *R. Parkerii*, *R. playfairianus* and *R. Swinhoei*. The best of the deciduous species with ornamental foliage are *R. giraldianus* and *R. thibetanus* (*Veitchii*).

Cultivation.—Though their cultivation in the ordinary way presents no difficulties, these Chinese Brambles respond readily to good culture of the soil. A rich loamy soil, well worked, and a mulching of decayed manure increase considerably the vigour and beauty of the plants. With the deciduous species, particularly those with ornamental stems, it is very desirable to cut out the old growths in autumn, to expose the full beauty of the previous summer shoots. Layering the shoots forms a ready means of increase, and those species which fruit freely may be propagated from seeds.

RHODODENDRON RUBIGINOSUM

ABOUT twenty years ago this and several other Rhododendrons were introduced by Messrs. Veitch from Western China, and it was soon seen that they were likely to prove useful additions to the various species which were already in cultivation. Growing about 3 feet high, *R. rubiginosum* is distinguished by its reddish brown stems and by its leaves, which are from 2 inches to 3 inches long, being covered with small, rounded, brown scales. The flowers are 1 inch to 1½ inches across, and are borne in small terminal heads. Their colour is rosy red, and when at their best they make a very bright display. It was one of the discoveries of the Abbé Delavay, and is said to be common on the Tsangshan Mountains in Yunnan at elevations varying between 6,000 feet and 7,000 feet. A companion plant which appeared about the same time from the same region is *R. yunnanense*. This often grows about the same height, though it may become much taller, and bears white Azalea-like flowers,

which are marked with red on the upper petals. Both plants are desirable sorts to grow in gardens where the dwarfier kinds of Rhododendron are encouraged. Where collections of such species do exist, they provide a never-ending source of enjoyment, for all are beautiful, and a very wide range of habit and variability in flower is exhibited. D.

THE ROSE GARDEN.

NOTES ON THE NEWER ROSES. TEAS FOR EXHIBITION.

(Continued from page 612.)

Mrs. Herbert Hawksworth (Alex. Dickson and Sons, 1912).—As seen growing at Newtownards this July I was very much struck with the beauty of this Rose. It is a flower of much substance and many petals, of a more globular form than is generally associated with a Tea Rose. It is pure white in colour, especially in the fully-developed flower, and when better known will be in much request among exhibitors, as weight, quality and perfection of shape are marked characteristics. It is a good grower, and the plants I saw of it carried plenty of flowers. It is sweetly scented.

Mrs. Hubert Taylor (Alex. Dickson and Sons, 1909).—This has been frequently exhibited this season by amateur and professional alike. A pale blush in colour, fading to white at the edge of the petals, yet it is distinct alike in colour and shape, although so reminiscent of the old

THE SLENDER WHITE STEMS OF *RUBUS GIRALDIANUS*.

Mme. Cusin that I have heard it described as a sport of that variety. I do not think, however, it is so, as the growth is very unlike it, being much strouger, and the leaves are frequently seven in number. It was awarded the gold medal at Luton in 1909, and is a good, reliable Rose.

Mrs. Sophia Neate (S. Bide and Sons, 1909).—This can hardly be said to have been frequently exhibited, but a plant in my garden this year produced such excellent flowers that I am tempted to include it here, at any rate as a variety worth trying. Its flowers are salmon pink in colour, of good shape when well grown, and the plant is of quite good habit.

Nita Weldon (Alex. Dickson and Sons, 1909).—This Rose has improved immensely with me. The first year I had it I was inclined to label it decorative or garden only; but I have altered my opinion of it, and useful as it is for these purposes, it cannot be ignored by the exhibitor. It found its way into a good many boxes this year. It is a pretty flower and gained the gold medal at the Royal Botanic Show in 1908; good habit and very free-flowering.

Recuerdo de Antonio Peluffo (Souper et Notting, 1911).—The only new Tea Rose of Continental raising that I feel justified in recommending for exhibition purposes. It is, I should say, of Mme. Constant Souper parentage; but this is pure surmise on my part. The four plants I have had of it this season have given me some excellent flowers, considering they were only grafted. It is pale yellow, with a Picotee pink edge to the petals, requires protection from wet, but it makes a large, bold flower of distinct merit.

W. R. Smith (Smith, 1908).—This, I believe, is an American-raised seedling, a very fine grower that produces large flowers, nearly white, tinged blush on the outside of the petal, that will, however, come split "sometimes." This is its only fault, but it admittedly is a serious one. Personally, however fine a bloom was as regards colour and size, if it had a split I should hesitate to stage it. Still, that is not everyone's opinion, otherwise we should not find so many split flowers as we do in looking round the exhibition boxes of the trade and amateur alike. Still, I am sure there are less than there used to be, and I put that down entirely to the fact that a feature of most of the new Roses is that they produce so many more perfect flowers per plant than the older varieties. It is a coincidence only that I have to close my notes on exhibition Roses with a variety that does sin in this respect, in that a certain percentage, and not a small one, of its flowers come split. If they did not, the Rose under notice would be entitled to be placed very high in the list of the newer Roses.

Next week I hope to commence my notes on the newer decorative, climbing and other Roses, which are now so highly appreciated for garden decoration and for cutting. These Roses have been wonderfully improved in recent years, and there are plenty of good varieties available.

Southampton.

HERBERT E. MOLYNEUX.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Continued from page 613.)

Soils for Larger Areas.—In the last chapter I had something to say concerning soils and crevices and the importance of having all such well charged as the work proceeds, and in a concluding word urged a freer use of grit and finely-pulverised rock for all high alpine of the tufted class. These are those which for the most part bejewel the rock faces of the earth, and these are the things which we should endeavour to imitate in our gardens. But, after all, it is but a phase of Nature's work, albeit an important one, and there are others demanding attention and study. I refer to the plants more suitable for larger areas, for colonising on slope or miniature ravine, and those freer-growing subjects, such as many of the hybrid Phloxes, Bell-flowers, Primulas and others that, so far as they inhabit Nature's rock gardens at all, have a

assuming always that the writer has himself studied the subject—should play the part of the finger-post, the operator doing his share, as already noted. The practical-minded writer will, however, be able to direct pretty clearly by citing some of

The Object-lessons of the Garden Itself. For example, the Phlox, Campanula, Primula or Saxifraga that has demonstrated its complete happiness, freedom of growth, flowering and hardiness when grown on the fringes of the choice border, or as a carpeter to something else, is not the plant we need take into the rock garden to starve; common-sense alone should dictate that we give it a liberal fare. Yet it is surprising how often such teaching is ignored. A large number of the silvery Rockfoils are so much at home on the so-called "flat rockery," or even in touch with fat garden soils, that they appear indifferent to that class of soil upon which they are found in Nature, and which, after all, might prove to be but the merest circumstance to which the plants have adapted themselves through the centuries. The

THE DRIPPING WELL IN THE ROCK GARDEN AT KEW HAS BEEN REPLACED BY A SERIES OF MINIATURE CASCADES. THE LEFT OF THE ILLUSTRATION SHOWS THE ALTERATION IN PROGRESS, AND THE RIGHT SHOWS THE WORK NEARLY COMPLETED.

preference rather for the richer pasture soils of the uplands than for higher altitudes and rocks alone. For such as these we may, without hesitation, prepare a greater feast, giving them a foot or 15 inches of rock-charged soil, leaf-mould it may be occasionally, or even manure of a kind—that type of it from which all insect-life has been eliminated by heat, and which is capable of being rubbed through a fine-meshed sieve by the hand.

The Habitats of Many Mountain Plants are, however, as varied as the plants themselves; hence no hard-and-fast rule can be laid down. Rather should the gardener study the conditions of the plant in its wild state, and, with such knowledge acting as guide, counsellor and friend, broaden and deepen it by experiment and observation. In these, as in other matters, there is nothing like the school of experience, and the lessons learnt therein will, I am fully persuaded, sink far more deeply into the mind of the earnest student than the gleanings from columns of text. The text-books—

Cotyledon Saxifrages, the Aizoons and others of the silvery set are instances of this soil indifference, these growing well and flowering freely in cool almost pure sand, heavy, clayey loam, and on rocky dry slopes where the soil is chiefly old mortar and rubble. Generally, however, the highest encrusted development has been noticed where the plants were associated with limy soils. Hence there need be no slavish imitation of Nature, remembering always that we garden for gardening's sake, and to get the most out of the material and conditions within our reach.

The Bog-inhabiting Primulas of the Himalaya, and those others of the Swiss and Tyrolean Alps, afford instances of the impracticability of laying down hard-and-fast rules of culture. Moisture, or those near equivalents shade or rich soils, are essential to the former, while moisture—the constant moisture of the bog—might prove harmful to the others. If, however, we take such Primulas as *marginata*, *viscosa*, *intermedia* and its rather

numerous following, we shall find these greatly benefited not only by rich soils, but by that frequent division which also ensures in the subsequent replanting a re-burying of the stem, which in turn promotes a renewed root activity near to the rosettes of leaves. In Nature the constantly-accumulating *débris* from the higher slopes acting as a mulch is the equivalent of the deeper planting, and is the more important to those types or species which incline to thrust their stems out of the earth. Those that do this perish at their bases in proportionate degree, the root-fibres being, given certain conditions, more or less an annual production. A phase in rock garden construction not yet touched upon is

The Miniature Cascade, which, while adding a distinctive feature, will also permit of the inclusion of a variety of plants not possible otherwise. That shown in the illustration on page 625 will give an idea of what is meant, the pictures side by side showing the start and the nearly finished work. The example in question

A YEAR OLD ROCK GARDEN.

A YEAR ago the ground on which stands the rock garden, a corner of which is shown in the illustration, was flat, uninteresting and weed-bestrewn. It was a narrow strip in an unmade garden. With pencil and paper a little sketch of winding paths, raised mounds and dry, stony water-courses was drawn out, attention being directed to the proper curves of the paths, avoiding any straight or formal lines. With no natural facilities for imitating mountain scenery, the plan adopted was first to trench the ground, then to collect all the stones from other parts of the garden, pile them in heaps where height was wanted, and dig out the paths as deeply as the lie of the ground allowed, using the level frequently to avoid depressions. The earth taken from the paths helped to raise the mounds, and more earth was added till they were sufficiently high. Then came the placing of the rocks, perhaps the most fascinating part of the undertaking, and requiring no little strength

THE FLOWER GARDEN.

SOME FACTS ABOUT THE TULIP MANIA.

(1634 — 1637.)

(Continued from page 615.)

I HAVE dealt in my first article with the apocryphal tales; the curious bargains that were sometimes made between buyer and seller for valuable bulbs; and the contributory causes, which were mainly two, viz., the keenness of the rich Dutch themselves to have the very best collections possible, and the long-continued demand from Paris for the rarest varieties to enable the young gallants there to make suitable offerings to their lady friends. I now come to the most interesting question of how sales were conducted during the period when the mania was at its height; for it must not be supposed, as it easily might be, that buying and selling were then the simple and ordinary processes with which everyone is familiar. When the mania really broke out in full force, such was the mad rush of everyone (nobles and chimney-sweeps, dames of high degree and serving-maids, weavers and learned men) to take part in the huge gamble that special provisions had to be made in order that business might be carried on with some sort of seamliness and order. In the mania area proper the usual avocations of the people were laid aside, and their whole time and energies given to the acquisition and disposal of Tulip bulbs, or, to be more precise as regards a great part of this exciting period, of the slips of paper which recorded their bargains; for if one thing is more certain than another, the actual possession of the bulbs was the last thing the gamblers wanted. High prices and specially choice varieties were known in Holland in the earlier years of the century, for a contemporary writer, Nicholas Wassenauer, has recorded how the celebrated *Semper Augustus* was sold in 1623 for "thousands of florins," and in the beautiful copper-plates of the famous Utrecht engraver Crispin le jeune. in the "*Hortus Floridus*," we have excellent illustrations of some of the best pre-mania flowers.

The inference is that the Dutch would be more or less familiar with the lucrative business of selling well-known kinds, and doubtless the fortunate possessors were just as much envied as Clusius had been a generation or two before, when he alone had Tulip bulbs to cultivate. Their readiness, then, to embark on this trade of getting rapidly rich is not so surprising. The lighted match was all that was wanted. It came in 1634, and gradually the fire burnt fiercer and fiercer until the culminating point was reached in 1636-37. It is impossible to trace in detail all the steps which led up to the elaborate systems of bargaining which eventually became *de vigueur* in their transactions.

To begin with, bulbs were bought and sold as they are to-day, and as they always had been previously; then a system of weights was introduced, of which the unit was an *azen*, a small weight less than a grain. A bulb would be sold at so much per *azen*, and as its weight was recorded when it was planted, the purchaser would have some idea of the price he

A SMALL ROCK GARDEN TWELVE MONTHS FROM THE DATE OF CONSTRUCTION.

is to be seen in the rock garden at Kew, and is taking the place of the old dripping well which has long existed there. The present erection will afford more suitable accommodation for plant-life, and those phases of it in particular that will be more in keeping with it than the old. Doubtless presently we shall see some of the hardy Filmy and other Ferns there, while the shelving rocks, so well shown in the picture, will lend themselves in a variety of ways to effective planting. As will be seen by the left-hand portion of the picture, the entire erection is in touch with soil, a not unimportant matter. The presence of an arrangement of this kind also renders possible the rock pool at its base, while an adjacent bog bed, or even a tiny streamlet, might each in turn contain its complement, and, while rendering it more complete, demonstrate, if in minor degree, the wealth, variety and resource of rock gardening as a whole.

E. H. JENKINS.

(To be continued.)

and discretion. Here, again, lines and formality would spoil the whole effect, the idea aimed at being the copying of a natural mountain.

The edges of the path should have especial attention, variety in stone and outline being essential. The picture gives a good illustration of this. In the planting the same theory should be followed. An example is shown in the double Daisies growing here and there, as if they had seeded themselves; in the uneven grouping of Sedums and Saxifrages; in the mass of Dianthus in the foreground.

It is wonderful how quickly the plants make themselves at home in the crevices and pockets between the stones; how they grow and spread, till, all of a sudden, you realise that the coarser-growing things are taking more room than their share, to the detriment of some precious pigmy. A most attractive place is the rock garden, but one needing constant attention.

EDITH DELVES BROUGHTON.

would have to pay. Lastly, this principle was extended, and the individual bulbs were no longer thought of, but simply so many azen of this variety or of that, say, of a Gonda or a Viceroy, were bought and sold quite irrespective of the fact whether the weight made up entire bulbs or not. To regulate the trade, now so many had left their usual occupations and were joining in the speculation, collegiums, or clubs, were formed in all the chief centres. The procedure in them was as precise and formal as it is in the Stock Exchange to-day. Two methods of transacting business were allowed. One was called "met de Borden" and the other "in het Ootje."

The former was a sort of sale by arbitration, in which the chief factor, from which it took its name, were two slates or tablets, on one of which, first of all, the buyer wrote down the amount he offered; and on the other the seller that which he was prepared to accept. These were submitted to two umpires, one chosen by either party, who made their award by writing it on the two tablets, which were then returned to the interested parties, who accepted it or not by their allowing it to remain or rubbing it out. The other system, "in het Ootje," was a sort of auction, in which the highest bid was recorded in a curious figure shaped like this:

After the bidding was over, the seller was free to take the sum offered or not, as he pleased. Under both systems provision was made for contributions to the funds of the collegiums. Eating and drinking were an inseparable part of the whole. I always think, when I see those glorious pictures of Franz Hals', in the gallery at Haarlem, how exactly he hit off one of the traits of his fellow-countrymen by his almost invariable introduction of some delicious morsels of food into his pictures. Certainly the inner man was well looked after by these collegiums, and it led to the inevitable result of attracting all manner of ne'er-do-weels, who came solely to partake of, under the guise of would-be purchasers, the good things provided. The crash came somewhat unexpectedly in the February of 1637, and it was in all probability hastened by the part these impostors took in inflating still more the already high prices, although before this date some few of the longer-headed ones had made stipulations in their bargains to protect themselves should there be a fall in prices. Once the bubble was pricked, events moved quickly, and with certain regulations promulgated by the States of Holland and West Friesland in the April of the same year, which defined the terms on which all contracts were to be executed, and with the finding of a Commission in the May following, the famous mania-time came to an end. JOSEPH JACOB.

[Owing to a telegraphic error the name of Tulip Admiral van der Eyck was wrongly spelt on page 615 last week.—Ed.]

WINTER WORK ON LAWN.

WHEN lawns are in need of attention it is a good plan to set about the necessary work as soon as possible after the cessation of mowing in autumn, for although it is possible to proceed with certain kinds of work until the middle or end of March, the earlier it is done the better. The lifting and relaying of turf may be done at any time when the weather is open, between late autumn and early spring, but if the ground to be relaid is to be used for tennis, croquet or cricket the earlier date should

the ground be poor, advantage may be taken of the opportunity to dig well-rotted manure into the soil, for it is an advantage to get the manure below the turf whenever possible rather than apply it as a top-dressing. Poor, weak turf may sometimes be wonderfully improved by being lifted, the ground manured and dug over and the turf relaid. One thing must be considered, however, when this is practised, viz., that the ground be thoroughly trodden before the turf is relaid, otherwise during the following year, after a machine or roller has been passed over it a few times, small depressions will appear,

which are due to uneven sinkage. Even in old lawns small hollows occasionally occur, particularly if trees have occupied the ground at any previous time. These small depressions have a disfiguring effect, for although a lawn with naturally undulating turf, following the general contour of the neighbouring land, is quite as beautiful as a perfectly level lawn, and even better suited to some gardens, it is a very different matter to a lawn spotted with tiny hillocks and depressions. In the event of such a lawn being in a very bad state, the most satisfactory result is gained by lifting the whole of the turf, forking over the ground, manuring if necessary, and relaying the turf after the ground has been properly levelled. But if the holes are few in number it is better to remove the turf from those regions, add the necessary amount of soil and relay the turf. In carrying out such work it is sometimes a workable plan to reduce hillocks and fill up holes with the soil so obtained, thus effecting a saving of labour and cartage.

People are often troubled with weeds in lawns, and during winter they wish to do something to improve the general condition of the grass for the following year. For the smaller weeds and moss the great point is to encourage the grass by every possible means. As a rule the weeds gradually gain the upper hand when the soil begins to fail, therefore steps must be taken to enrich the soil before it will be possible to cope with the weeds. True, it is possible to kill a certain number of the weeds by applying lawn sand, but no permanent good will be done until the ground is enriched and made more suitable for the grass than for the weeds. To set to and clear even an acre of lawn from such a weed as the

TULIPS OF THE MANIA TIME. THE BULBS OF THESE VARIETIES WERE WORTH MUCH MORE THAN THEIR WEIGHT IN GOLD.

be selected. At the same time any necessary repairs should be done to playing areas or to portions of lawns which may have become badly worn during summer.

Ordinary lawns which are not subjected to heavy wear may have weak places renovated by pricking the turf over with a fork and inserting a little seed during September, but turf which is subjected to hard wear requires something further. Any part where the grass is weak should be lifted, the ground forked over and levelled and new turf laid. Should

Daisy, either by lawn sand or by hand-weeding, is an expensive and almost hopeless task without the grass is encouraged, for if 10,000 weeds are removed one winter the same number may appear the following spring from seeds lying dormant in the earth. The same remarks apply to moss, for many days may be spent raking the moss out with an iron-toothed rake—the means usually adopted—but if something further is not done the results will be unsatisfactory. One of the best dressings that can be applied to

lawns on poor soil is good loamy soil free from weed seeds. If applied early in the winter, a depth of quite 2 inches may be spread over the turf, but steps must be taken to stir it about frequently, otherwise it will become caked, and the grass will suffer. A chain harrow passed over the surface on a dry day is usually all that is needed, or, on a small lawn, the work may be done with a strong iron rake. Anyone who has not applied such a dressing will be surprised to find how soon the soil disappears among the grass. Quite as good a dressing as soil is furnished by mud taken from a lake, pond or ditch. This should be left in a low heap for a few weeks to dry somewhat, and then be spread over the grass. Until dry enough for the harrow it may be stirred occasionally with forks. Like soil, it soon disappears. Well-decayed farmyard manure is also a good dressing, while the screened residue of garden fires may be applied with advantage. Ground which is deficient in lime may be made more suitable for grass by the addition of lime, while a sowing of bone-meal is also a good thing. Bone-meal, basic slag and other manures of a like nature are more suitable for grass which is fairly free from weeds than for very weedy ground. Basic slag, it must be remembered, gives better results the second summer after sowing than the first; therefore it is a good plan to make a light sowing in spring, say, about seven pounds or eight pounds to the square rod after the application of soil or manure during autumn or winter. Spent hops and soot are good subjects to apply in wet weather in spring, for they act quickly, and give the grass a little extra fillip at a necessary time.

Coarse weeds, such as Plantains and Dandelions, cannot be outgrown in the same way as smaller-growing kinds, therefore the best way of dealing with them is to pull them up, taking care to extract the whole of the rootstock. Cutting off is of little use, for dormant buds start into growth, and in a short time the plants are as vigorous as ever. In the same way applications of salt to the crowns are not always effective, for unless the rootstock is killed new growths are sure to appear sooner or later. The extraction of such weeds leaves a considerable number of holes in the grass, which should be filled in with soil free from the seeds of weeds.

The spread of weeds in lawns is assisted to some extent by mowing without collecting-boxes on the machines. Where the grass on lawns is of a coarse character an occasional dressing of sea sand should be given. This encourages the finer grasses, which in time take the place of the stronger ones. When a dressing has practically disappeared the lawn should be raked over for the purpose of removing stones and other rubbish, after which it should be brushed with a good besom and well rolled.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Miss A. Brooker.—A decorative Japanese variety with somewhat incurving florets and of rich chestnut crimson colouring. The habit is erect and good. Messrs. James Veitch and Sons, Limited, showed pot-grown examples not more than 3 feet high, Messrs. Wells, Limited, Merstham, having a handsome vase of blooms. A useful addition.

Chrysanthemum Eric Wild.—This is virtually a pink-coloured *Mensa*, and we are of the opinion that no higher tribute could be paid to a single-flowered variety.

PRUNUS MIQUELIANA, A NEW HARDY WINTER-FLOWERING SHRUB.
(About two-thirds natural size.)

Chrysanthemum Mrs. Wingfield Miller.—A single-flowered variety. The colour is rose pink, the broad ring of white at the base of the florets rendering it distinct and attractive. These were from Messrs. Wells, Limited, Merstham.

Prunus miqueliana.—There would appear some doubt as to the authenticity of the name here given, and which for the moment is attached to one of the most elegant and captivating of the winter-flowering members of this beautiful race of plants. The plant assumes a twiggy bush or tree, the branches studded with two to three flowered clusters of starry white blossoms, arranged barely an inch apart on elegant leafless sprays. At maturity the filaments assume a reddish carmine tone,

which enhances the value of the plant (see illustration). It is said to be capable of enduring with impunity several degrees of frost later, when in full flower. From Colonel Stephenson R. Clarke, C.B., Borde Hill, Cuckfield, Sussex.

Asplenium divaricatum elegans.—A plant capable of much useful service from the market-grower's and decorator's point of view. It has more finely-divided fronds than *A. bulbiferum*, and is of more erect carriage. A graceful and beautiful plant. From Messrs. J. J. Parker and Co., Whetstone.

Carnation Mrs. A. F. Dutton.—A pretty and attractive variety, said to be a sport from *White Perfection*, though as shown it is certainly much larger. The predominating colour shade is apple blossom pink, rosy and warm at first, and, paling later at the edges of the petals, is effective and pleasing withal. From Mr. A. F. Dutton, Iver, Bucks.

Carnation Bonfire.—An American-raised variety of medium size, and of a colour shade that is all aflame in the sunlight. Mingling with the crimson-scarlet pervading the flower as a whole, there is seen a touch of ruby crimson, which, while distinguishing it from all other reds, endows it with fire and life. From Messrs. William Wells, Limited, Merstham, Surrey.

NEW ORCHIDS.

First-class certificates were awarded to *Laelio-Cattleya Golden Oriole Ruby*, shown by Lieutenant-Colonel Sir George Holford, K.C.V.O.; and *Odontioda Latona Fowler's variety*, shown by J. Garney Fowler, Esq.

Awards of merit were granted to *Cypripedium Viking*, from Lieutenant-Colonel Sir George Holford; *Sophrö-Laelio-Cattleya Carna*, from Messrs. Charlesworth and Co.; and *Cypripedium Eurybiades*, from Sir Trevor Lawrence, Bart., K.C.V.O. A grand specimen of *Sigmatostalix radicans*, also shown by Sir Trevor Lawrence, secured a cultural commendation.

NEW FRUITS.

Apple Steyne Seedling.—A capital late dessert variety of fine

flavour and colour, resembling a large fruit of Cox's Orange Pippin. Shown by Lady Thornycroft, Isle of Wight.

Apple Crawley Beauty.—A late culinary Apple of unknown parentage but of excellent quality. We are informed that this is a noted local variety found in cottagers' gardens in the neighbourhood of Crawley. Shown by Messrs. Cheal and Son, Crawley, Sussex.

Apple Winter Banana.—A Canadian variety shown by the Government of British Columbia. The flesh is firm, juicy and of far superior flavour to the general run of Canadian Apples.

GARDENING FOR BEGINNERS.

THE LEATHER JACKET AND ITS ERADICATION.

THE daddy-long-legs, or the crane-fly, as it is variously called, in allusion to the length and slenderness of its six legs, is an insect known to everyone. It is numerous enough almost everywhere to call attention to itself during the summer and early autumn months, flying over grasslands or sheltering in sheds or rooms in wet

chrysalids being easily recognisable from their elongated form and curious projecting spikes (Fig. 5). From these the perfect fly (Figs. 1 and 2) emerges in summer.

One noticeable peculiarity in their habits is their liking for damp places. This suggests the desirability of careful and thorough drainage. Their ravages are very rarely experienced in well-drained situations, especially if there is no tendency to acidity through insufficiency of lime in the soil. Birds of many kinds feed upon them, and the numbers consumed by thrushes, starlings, lapwings, rooks and gulls are enormous.

Nothing that can be added to the soil can be said to kill them without fail, though probably dressings of substances containing naphthalene do a good deal towards clearing them away, and, if it could be applied cheaply, carbon bisulphide would be an excellent remedy. Efforts have, however, to be directed mainly towards prevention, and the encouragement of insectivorous birds and attention to drainage are important points in this direction. The cleaner

unforeseen that often happens, and from one packet of seed a variety of colours, both in single and double flowers, may be obtained, even though the seed may have been collected from one plant only. It is however advisable to procure seed from a reliable source, for by this means only is one likely to obtain a good strain of seedlings. Single varieties are, as a rule, useless, and should be discarded; but double varieties, if worthy, may be perpetuated by layering or from cuttings and pipings. There is a common failing among double-flowered seedlings, viz., a split calyx, owing to the number of petals being too great for the green calyx tube, with the result that the latter bursts and the flowers present a very untidy appearance.

It is usual to sow seed, say, in late March or April, and these notes serve to remind one in good time for the work to come. The seed should be sown under glass, preferably in a warm greenhouse, using well-drained pans and a compost of sandy loam and sifted leaf-soil for the purpose. The pans should be finished off with a level surface of finely-sifted sandy soil, and the seed just covered with silver sand. It is well to place a piece of glass over the seed-pan to keep a uniformly moist temperature, and under these conditions germination will take place in a week or a fortnight. As soon as germination has taken place, the glass should be removed, keeping the seedlings in an airy place and as near to the glass roof as one reasonably can. When large enough to be handled, and after being well hardened off, the seedlings will be ready to plant in open beds, and if the beds have been enriched with fresh loam, decayed manure and lime rubble, so much the better. By the end of September the seedlings may be transferred to their permanent quarters in beds or borders, and here they may remain until the following year, at which time they can be depended upon to reveal their secret forms and colours.

1, MALE DADDY-LONG-LEGS; 2, FEMALE DADDY-LONG-LEGS; 3, EGGS; 4, GRUB; 5, CHRYSALIDS.

weather. There are several species known in Britain, and their various times of hatching-out prolong the season over which the insects are on the wing. *Tipula oleracea* is about in May and June, *T. paludosa* in August and September, and these are the two common species. The flies themselves do no direct harm, and they form an eagerly-sought food of many birds, such as starlings and thrushes, which may often be seen snapping them up while flying over the rough herbage of a headland, or about a hedge or over a lawn.

The flies lay a considerable number of blackish eggs, nearly always among rough grass and weeds, though apparently sometimes among cultivated plants. The eggs hatch within a fortnight or three weeks, and give rise to the grub called the leather jacket. Occasionally leather jackets are confused with surface caterpillars or with wireworms, from both of which they differ in the absence of feet. Fig. 4 shows their shape and size when full grown. The mouth is at the pointed end, and at the blunt tail end are a number of curious processes, and these characters help to distinguish them from other soil grubs. In colour they are a dark grey, sometimes almost black, and have a rather tough skin, from which their common name has been derived. They feed on the roots of grasses and various plants, such as Carnations, Strawberries and so on in the garden, within a few inches of the surface, going deeper in cold weather. When full fed they become chrysalids of the same dark tint in the soil, the

the cultivation, too, especially about those too frequently neglected corners of gardens, hedge banks and the like, will help to keep the flies from laying their eggs, and, where it can be used, a heavy roller will crush numbers of the flies when they are hiding in rough herbage and in long grass.

SCIENTIST.

CARNATIONS FROM SEED.

THE raising of Carnations from seed is a delightful and fascinating pastime, owing to the fact that one is never quite sure what the results will be. There is a glorious uncertainty about the operation, and one may become possessed of varieties of hitherto unknown colours. It is the

A VASE OF SEEDLING CARNATIONS GROWN BY AN AMATEUR.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Bulbs and Tubers in Store.—Time may profitably be spent at this season of the year in occasionally examining the various subjects that are resting, such as Dahlias, Begonias and Gladioli. A dry, cool place is required, and should any of the bulbs be decaying, remove them at once. If taken in time, decay may be arrested by cutting away the diseased part and dusting powdered charcoal on to the clean-cut portion.

Preparation of the Ground.—As with all other departments of gardening, there is nothing like a good start, and it is at this season, when work is slack, that attention may be directed towards the improvement of the soil and obtaining a greater depth of good soil, so that the plants are better able to withstand a period of drought. The positions for Sweet Peas and Dahlias, to mention two commonplace subjects, should be well prepared, have plenty of manure added, and the surface of the ground be left rough. If the soil is deficient in lime, give the surface a good sprinkling and apply any burnt garden refuse.

Tritomas or Kniphofias.—These are none too hardy in many places, but are worth a little care and attention to preserve them through the winter months. The plants will benefit by a good covering of a loose material, such as flaky leaf-mould or short strawy litter, and, in the event of extra sharp weather, a further covering of Bracken may be given them.

The Rock Garden.

Gentiana acaulis.—We have just replanted two beds of this subject, which has occupied the same position for a number of years on either side of a garden walk. The old soil, which had become impoverished, was taken out to a depth of 18 inches, some rough drainage placed at the bottom and new rooting material afforded, and the old clumps divided up and replanted, making them very firm.

The Shrubbery.

Early-flowering Shrubs.—Those that brave the elements in the New Year are particularly welcome, and when planting in the mixed shrubberies the selection should include some that flower at that season in some form. Quite one of the most interesting, and easily trained to a support, is *Jasminum nudiflorum*. *Lonicera Standishii* is commencing to open its pretty flowers at the time of writing, and will continue to bloom till quite the end of January. *Hamamelis mollis* is in flower about Christmas, and continues fresh throughout January. *Prunus davidiana* and *P. d. alba* commence about the end of the first month. *Daphne Mezereum* and the white form bloom during January and February. Then towards the end of February or early in March that small tree or bush, *Parrotia persica*, begins to unfurl its quaint flowers. *Ribes laurifolium* is new, but will make a grand early-flowering subject for the rockery, being absolutely hardy and unlike any of the others. *Chimonanthus fragrans* (the Winter Sweet) succeeds best on a warm wall, where it will fruit freely as well, and in such a position is often in bloom by the end of January, though it is also hardy here as a bush. During March the *Corylopsis*, *Cornus mas*, with its varieties, with additional charms by reason of their variegated foliage; *Ribes sanguineum* and varieties *carneum* and *atrosanguineum*, the well-known Flowering Currants, *Cydonias*, and the many *Prunuses*, including *Pissardi* and the varieties of *persica*, and the Almonds, *Spiræa Thunbergii* and *Forsythias* will all be in flower.

Plants Under Glass.

Plants in Rooms.—Especially at this season of the year, when thoroughly well warmed at night and probably the windows thrown wide open early in the morning, decorative subjects, even if well hardened, are apt to suffer. Before taking them indoors, especially if from a warm house, they ought to be transferred to a cool one first for twenty-four hours, and the foliage plants be frequently changed.

Ficus repens.—This is a splendid subject for covering the walls of houses, thriving in almost any site and clinging very closely to the walls. It has a neat appearance and, when kept syringed, grows freely.

Stag's-Horn Fern.—On such a background as a greenhouse wall *Platycteriums* look most attractive and seem to thrive. The best way of establishing them is to make a pocket of virgin Cork, securing it firmly to the wall by means of wire. Then fill up with a mixture containing plenty of rough peat. If the plant does well it will eventually support itself.

Fruits Under Glass.

Suckers in Peach Trees.—These are often a continual nuisance and make the house appear very untidy. While the trees are dormant and when attention is being given to the borders, trace the suckers down as far as possible to their origin and cut them off. To keep pulling them when green only causes them to come thicker again. Damaged roots are the cause of them, and the importance of cutting away any roots that are bruised from the under side cannot be over-estimated.

Pot Strawberries.—If the plants in pots for forcing are well plunged in leaves or ashes so that the pots are secure, they will take but little harm. They are best protected from heavy rains, however, and should exceptionally cold weather prevail, add further protection.

The Kitchen Garden.

Chicory.—The roots of this salad may now be forced with the greatest of ease where a warm place is available.

Asparagus.—Where good strong crowns are available, this may now be forced on mild hotbeds or in a warm structure with bottom heat. But in cold frames on a hotbed excellent produce may be obtained. Place the roots thickly on a little soil, just cover them, and keep as near to the glass as possible. Place a lining of warm strawy litter round the frame.

Broccoli.—Look through these and make the curds quite safe from frost by bending down the leaves over them, and when large enough, transfer to a safe place.

Late Turnips.—Mould a little soil up round the roots of these. Such plants will probably give a few good dishes of greens later on.

The Hardy Fruit Garden.

Fruit Trees on Walls.—When fruit trees have been nailed to walls for a number of years, the face of the walls becomes much knocked about and makes a splendid harbour for insect pests. The trees will benefit by being taken down and well cleansed, loosely tied up, and the walls well dressed as well with a strong insecticide, taking care that too much does not reach the roots. The use of strained wires on walls has much to recommend it. Where shreds are employed for nailing, I would recommend the use of those known as Dean's Medicated, as they are both durable and distasteful to insects. E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Iris susiana.—Though quite hardy, it does not harm, but rather benefits the plants to place some rotted manure among the pushing shoots. It is remarkable how, as November returns, the new growths begin to push up from the ground, but it is no doubt during the early spring months that the flowering growths for another year are produced.

Schizostylis.—This Cape plant is doubly gay, owing to the absence of floral competitors. Unfortunately, it is not quite hardy in the North, and in cold localities it is worth lifting and preserving over the winter in a frost-proof building. It succeeds well here on a dry, warm position, and also in the rock garden.

Red Valerian.—This "weed," of which there are some desirable colour variations, is another satisfactory plant for blooming into the winter. It must be provided with a dry soil and warm position to get it in flower so late, and the plant be cut over in summer. It is also suitable for wall culture.

Pampas Grass.—Two months ago it seemed as if this handsome Grass would fail to flower. At the time of writing, however, the clumps are well supplied with plumes. For the sake of these some people strip the plants as soon as the plumes

are fit to cut, which seems a wasteful thing to do. Where frosts are known to be intense, mats or other protecting material should be held in readiness to cover the plants. Here they are often frosted, but always make good the next season's growth, though unprotected in winter.

Shrubs.

Romneya Coulteri.—Still producing its paper-like blooms, this also should be protected during severe frost, for though the current year's shoots may be, and often are, destroyed, the base of the plants may be preserved, provided a dry soil is chosen and protection given.

Lonicera Standishii.—This is now in flower and will continue producing blooms for many months. It is grown on south walls here and varies considerably in the time of flowering, according to position. On a terrace wall it never flowers till spring. The same thing occurs with

Jasminum nudiflorum, which is now flowering in some positions, the buds not being formed on plants in less exciting situations. This is an invaluable plant for the gardener, the long flowering sprays, whether in bud or flower, being always acceptable for vase-filling. The shoots strike root as freely as a Gooseberry, and soon grow into sizeable plants, either for wall-covering or for bushes.

China Roses.—Large unpruned bushes almost every year produce quantities of their lovely pink blooms even into the winter. Our latest and best are produced in a position shaded by large Laurels, and one that no one would for choice choose for Roses. Unfortunately, the vicissitudes of seasons have left nothing but the stock of some. It is worth noting that it is not wise to plant budded Roses for ordinary purposes. Most of them root with facility from cuttings and, if planted deep enough, the frost that will kill such things must be severe indeed.

The Plant-Houses.

Salvia splendens.—Once these are past their best, they are not worth preserving, but should be thrown out, keeping only enough to provide cuttings for another season's supply.

Marigolds.—Those who have not seen these in the dark time of the year would be surprised to see how brave they look as pot plants. Their great foe is mildew, and they flower all the better for being rather under-fed and under-watered. Besides the beauty of the flowers there is always that spicy scent, of which many people are fond—so fond that at one time the blooms were eaten.

Chrysanthemums.—These are much later than usual, which is a condition that is very welcome, as it means a nice lot of bloom well through January. The late plants must, however, be very carefully dealt with, over-feeding and over-watering spoiling the blooms for cutting, and mildew is always a danger to be reckoned with. Cuttings are now ready, but for ordinary purposes it is doubtful if there is any advantage in taking them before the advent of another year.

Tulips.—We look for the earliest Tulips about this time, *Proserpine* being the most reliable forcer and so much superior to the *Duc Van Thol* group that I have not grown any of these for some years past. Few plants are so little affected by bad treatment as these. It is quite usual to shake the soil from the roots and sometimes to shorten these and plant them in fancy receptacles for decorative purposes. I find they live as long as those undisturbed in any way. Heated rooms, however, quickly destroy the petals.

The Fruit-Houses.

Guavas.—These are esteemed for preserving. The plants succeed very well on the back wall of a late vinery, in which the fruit will ripen in September. I occasionally cut back some of the stronger shoots; this causes the production of many young and vigorous ones, which carry much finer fruits.

Cutting Grapes.—Though Grapes can be preserved well on the Vines for a long time, it is an expensive method, and no hunches need be allowed to hang any longer where there is a dry room which can be kept at an equable temperature in which to store them. It may be noted that either end of the shoot may be placed in the water when bottling them. The value of this is that in the case of *Lady Downe's*, where the bunch is sometimes quite close to the main rod, the shoot can be cut close to the bunch and the part beyond it placed in water.

R. P. BROTHERSTON.

Tynninghame, Prestonkirke, N.B.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ROSES AND LAVENDER (Grafton).—We fear the width of the border will preclude the carrying out of the suggestion to which you refer, unless the Lavender bushes were planted as a bordering and trained outwards on the path, should such exist. In so small a compass there would be no better way than arranging the Roses alternately for the present, about two feet apart longitudinally, and not more than 18 inches asunder anglewise. If this were done, the Lavender bushes could be arranged rather closely to form a bordering, though it might be necessary to prune them from time to time to keep them within bounds. Should a grass verge exist at the margin, the planting of the Lavender would be impracticable. In that case we would suggest a bordering of Tufted Pansy Bullion or Florizel.

PLANTS FOR BORDER (G. B.).—If you wish for a border of summer flowers, you could hardly have in the space you name a more effective one than that made by Antirrhinums (Snapdragons), which, in Tom Thumb, intermediate and tall varieties, would make a grand show. The plants range from 6 inches to 3 feet high, and give shades of yellow, pink, crimson and orange in each section. These plants could be raised from seeds sown in January or February in slight heat under glass, and potted on and planted out in early April should do quite well. By employing two colours of each section, a great bank of blossoms would be formed. Snapdragons do not require a very rich soil, but it should be deeply tilled, notwithstanding. For flowering during late summer and early autumn, you might, with generous cultivation of the soil, plant Phloxes, Pentstemons—these to be raised from seed like the Snapdragon—Italian Starworts, Carnations, Michaelmas Daisies and the like. Again, seeing that you have Roses at the back, why not plant the border with dwarf Roses, and, if needs be, carpet the soil with Tufted Pansies? In our opinion, however, either the Pentstemons or the Antirrhinums would make the best show at the smallest cost, and, with a little intelligent care, are easily cultivated.

TREES AND SHRUBS.

REMARKABLE WILLOW TWIGS (R. G. J. R.).—The curious Willow growths sent for examination are flower catkins which have developed abnormally. It is difficult to say what may be the cause of the condition, but it probably originated through the puncture of insects or some other small injury. While such abnormal growths are not common, they are sent for examination two or three times a year, as a rule. A parallel case, but on a larger scale, is the formation of the large, curiously contorted masses of branches found on Birch and other trees, which are familiarly spoken of as "Witches' Brooms."

HEDGE OF CUPRESSUS LAWSONIANA (L. G. F.).—As your hedge has only been planted about a year, there is no immediate necessity for cutting the plants into shape, and you would be well advised to leave the work alone till next April. If you do the pruning now, no new growth will take place until next year, and the clipped plants will look ugly all the winter. By pruning in April, however, new shoots will appear almost at once. It is only by repeated pruning and care that you can keep the top horizontal and the sides vertical, and it will probably take you several years to obtain this condition. A gauge could be used for the sides and top, but it is probable that you will be able to work quite as well by the eye. Do not clip with shears, but use a knife or secateurs.

SHRUBS FOR SHADY PLACES (L. B. W.).—The following subjects are likely to prove satisfactory: Arbutus Unedo, Rhododendrons and Azaleas in variety, Berberis stenophylla, B. Darwinii, Hydrangea Hortensia, Spiraea arifolia, S. arguta, Potentilla fruticosa, Escallonia macrantha, E. philippiana, E. lanylevansii, Cotoneaster frigidus, C. buxifolia, and common Holly. It depends entirely upon the object for which the Spiraea is required as to whether S. arifolia (correctly S. discolor) or S. arguta is chosen. The former grows 10 feet high and blooms in July; the latter grows 5 feet high and blooms in April. Both are excellent shrubs. If you wish for a

shrub with a long period of beauty, a group of the golden-leaved Cornus Spæthii would be a good shrub to plant.

SHRUBS FOR BORDERING A PATH (J. T. O.).—The following shrubs will be likely to suit your purpose. All are easily grown if given good loamy soil which has been well worked, and all flower freely. Olearia Haastii, a compact-growing evergreen 3 feet to 3½ feet high, with small leaves and bearing white flowers freely in July and August. Berberis Darwinii, a bush 4 feet to 6 feet high (can, however, be kept any height by pruning), with small evergreen leaves and orange-coloured flowers in April. Choisya ternata, an evergreen bush up to 8 feet high and kept to 3 feet or 4 feet by pruning, flowers white, fragrant, produced in May. Philadelphus Lemoinei, deciduous, 3 feet high, flowers white, fragrant, borne in June. Diervilla Eva Rathke, 3 feet to 4 feet, deciduous, crimson flowers, borne from May to August. Syringa persica, a small-growing Lilac, 2 feet to 4 feet high, flowers lilac, fragrant, produced in May. It is probable that Kalmia latifolia would not succeed with you. When at its best there are few more beautiful objects, but unfortunately it is fastidious as to its surroundings, and for one place where it grows well there are fifty places where it is not a success. The plants mentioned above are all likely to grow well in ground which would suit an Apple tree or Gooseberry bush.

THE GREENHOUSE.

CLIVIA FAILING (Mrs. A.).—The reason of your Clivia behaving in the way it does is that the plant is subjected to too low a temperature and too great an amount of atmospheric moisture. The condition of the roots, too, may be at fault, and this would tend to make matters worse. If the roots are not healthy, the plant should be repotted next spring, immediately after the flowers are past, using for the purpose a compost mainly made up of good loam, lightened by a little leaf-mould, small nodules of charcoal and silver sand. Clivias are seen at their best when they are kept in a light, buoyant atmosphere, and in a structure where a minimum temperature of 45° is maintained.

PELARGONIUM LEAVES FOR INSPECTION (E. S. S.).—The leaves sent show marked traces of having been attacked by aphides or green fly, and these pests are, no doubt, the primary cause of the trouble. The injury was, in all probability, caused when the leaves were still young, and, as they developed, the punctures made by these insects become larger. Another point borne out by the appearance of the leaves is that the plants have apparently been kept too close and in too moist an atmosphere, for a free circulation of air is very necessary for the successful cultivation of Pelargoniums. We should not advise you to do away with the plants, as we consider that, by keeping them clear of insect pests and allowing them plenty of air, the trouble will be cured.

CHRYSANTHEMUM: YELLOW SPORT (W. F. H.).—From what you tell us of the yellow Japanese Chrysanthemum bloom sent to us for information, we should regard this as a root sport from the white sort named Miss Maud Jefferies. It is not at all an uncommon freak on the part of Chrysanthemums to sport in this manner, and we are very much disposed to think you will have no difficulty in perpetuating it. To make assurance doubly sure, embed the stems of some of the plants in light soil on the greenhouse bench, and propagate the shoots that are evolved. Also propagate the basal shoots from other plants having yellow flowers, and next year will prove, by its results, that you will have certainly fixed this sport in some instances, if not in every one.

PLANTS FOR A GREENHOUSE (J. T. H.).—The back wall should do for Roses; but, even then, so much depends upon circumstances, of which we have no knowledge. In all cases, five minutes on the spot with a practical man will be of more service than any advice we can give without knowing more particulars. If you grow Roses, it will be very essential to keep them absolutely clear of green fly, as these soon cause a great deal of damage. You mention that there are plenty of shelves, and such being the case, they could be utilised for flowering plants of various kinds during the summer and for bulbs in the spring. Again, you might, in the winter, force Rhubarb and Seakale therein, while an early crop of Dwarf Beans would supply something for the table. One good piece of advice is, do not aim at too many different things in the same house, as various plants require varied treatment.

CACTI (X. G. H.).—Many of the Cacti are adapted for growing in a living-room in London, as the dry atmosphere, the bane of most indoor plants, does not affect them to anything like the same degree as it does most classes of plants. A good light position is essential, and the more direct sunshine they get, the better they will, as a rule, flower. The most suitable potting compost for Cacti consists mainly of good loam, lightened by an admixture of brick rubble, broken small, and silver sand. From September to March watering should be sparingly done. At other seasons the soil may be kept moister, but stagnant water must never be allowed. In making a selection of the best for window culture, the Phyllocacti form quite a race by themselves, being of fairly tall growth, with large, gorgeous flowers borne during the summer months. Some members of this section are occasionally to be seen in cottage windows, as is also the Rat's-tail Cactus (Cereus flagelliformis), with long, pendulous growths studded with rose-coloured blossoms. Many of the smaller Cacti, such as the different Mammillarias, Echinocactus and Echinocereus, are of strange appearance, and will flower under favourable conditions.

ROSE GARDEN.

THE SEVEN SISTERS ROSE (A. R. B.).—There is confusion as regards the correct name of this Rose. Some think it is the De la Grifferaie, one of the multifloras, and now used as stock; but its flowers are pink. Others believe it is the Félicité Perpétue, and we believe the latter is the correct variety.

ROSES AND COLD GREENHOUSE (A. G.).—You can most certainly grow good roses in your cold greenhouse. You have a good border of rotted turf and horse-mannure, and we should advise you to trench this over and work some basic slag into the lower soil at the rate of 8oz. to a square yard. If you could deepen the border to 3 feet it would be all the better, looking to the future needs of the Roses. As you plant, give each bush a handful of bone-flour, scattered just beneath the surface soil and well distributed. Procure plants from the open ground—good bushy stuff on the Briar; and you could have one or two standards if you cared to do so, also one or two to train as columnar or pillar Roses.

FRUIT GARDEN.

YOUNG MAY DUKE CHERRY TREE (J. M.).—Could you not make a rough-and-ready provision for protecting the blossom next spring by making a framework round the tree of rough poles, on which the protecting material could rest? Old sheets, mats or tiffany of any sort would do, covering the tree over every night when frost is apprehended, and taking them off in the daytime, doing this till danger of frost had passed.

SPRAYING APPLE TREES (L. J.).—Spores of Fusidium dentriticum are about and active from March to October, perhaps longer. The affected shoots are best pruned off in the winter, but in case any are left, the spraying with copper sulphate (1lb. to twenty-five gallons of water) is resorted to in February. The spraying with Bordeaux mixture is to prevent the growth of spores on new leaves and fruits, and as these are active during the whole growing season (but most in the early part), spraying with Bordeaux mixture must be done at intervals.

DAMAGE TO APPLE TREES (J. R.).—The damage done to the foliage and the failure of the Apples to ripen are due to some extent to the adverse weather at about the time the Apple buds began to burst, and largely, as you suggest, to the attack by aphids. If an attack is likely to occur in spring it is easy to foretell it, for careful examination of the shoots during the winter will reveal the black, shiny eggs of the insects on the young shoots. Spraying with a caustic wash at about the end of February will lessen the number of those that hatch, and then spraying with Quassia and soft soap as soon as hatching occurs will check the trouble another year, so that an attack need not be feared, as it will not come until winter forms occur, and not before the middle or end of May, when the trees will be better able to withstand an attack.

PEAR LEAVES FOR INSPECTION (J. E. W.).—The insect that attacked the Pear leaves and devoured their upper surfaces is known as the Pear slug, and is the larva of the Pear and Cherry sawfly. It is black during a part of its life and has a slimy skin, and this has earned for it the name of slug; but, like most other true insects, and unlike the slug, it becomes a chrysalis, dropping to the earth and burying itself for the purpose. It hibernates in this form during the winter, and the perfect four-winged fly emerges in summer. The best method of dealing with it is to spray with lead arsenate, or to dust the leaves with lime on two occasions at intervals of two days. The latter measure has the effect of causing the larva to shed its skin twice in such rapid succession that the effort destroys it.

KITCHEN GARDEN.

INJURY TO CELERY (Mrs. A.).—The cause of your Celery being blighted is that the plants are very badly attacked by the Celery fly—to such an extent, indeed, that they are absolutely spoilt. The fly is but a small one, which deposits its egg on the leaves. After a short time these eggs hatch into tiny maggots, which commence to eat the chlorophyll, or green matter, of the leaves, thus greatly weakening the plants. When the evil is first noticed, these little white maggots may be seen carrying on their work of destruction between the two surfaces of the leaves. If few in number, they can then be killed by a nip between the finger and the thumb; but in the case of a bad attack this is, of course, impossible. The main point is to keep the fly from depositing its eggs on the plants, for which purpose soot or lime may be sprinkled on the leaves while they are damp. The two ingredients should not be mixed, the soot being more generally preferred.

MISCELLANEOUS.

WINTER TREATMENT OF LAWN (Mrs. Nains).—You will find this subject fully dealt with on page 627 of this issue.

ABNORMAL ANTIRRHINUM (W. R. Ward-Jackson).—The Antirrhinum sent is certainly an extremely curious one—more curious than beautiful. The inflorescences had developed in the normal way so far as bearing numerous lateral buds was concerned, but there they had failed. The flowers had not become green, as in so many instances, but instead of petals and so on, short leafy shoots had been developed, the leaves being very small compared with the normal ones. This kind of thing—replacement of flowers by leafy shoots—is sometimes due to external conditions, but if it were so in the present case, it is difficult

to see why other neighbouring plants were not also affected. It would rather appear that for some unknown reason the seedling had been born with this peculiarity innate. It would be extremely interesting to see whether the plant behaves similarly next year, or whether cuttings from it do so.

NAMES OF FRUIT.—W. F. N. C., Southampton.—Apple Royal Nonsuch and Pear Marie Louise.

NAMES OF PLANTS.—Regular Reader.—See next week's issue.—*Veronica*.—Small specimen, *Viburnum Tinus* (Laurustinus); large specimen, *V. T. lucidum*; *Veronica speciosa* hybrid, probably a little tender on the East Coast.—C. W., Sunderland.—1, *Linaria Cymbalaria*; 2, *Sedum sarmentosum variegatum*.

SOCIETIES.

THE PERPETUAL CARNATION SOCIETY.

The winter show of this society was held in the Royal Horticultural Hall on Wednesday, December 4, the non-competitive exhibits having been staged on the day previous in conjunction with the Royal Horticultural Society's meeting. That the society is making progress is fully evidenced by the excellent display of Carnations, making quite the best exhibition yet held by the society. There was a good attendance of visitors present during the day, and quite a keen competition in many classes.

OPEN SECTION.

One of the most attractive classes was that consisting of a table of cut Carnations arranged on a space 10 feet by 3 feet, with foliage, arranged for decorative effect. Mr. C. Engelmann, Saffron Walden, secured leading honours with a very handsome display, which included *Lady Northcliffe*, *Sunstar*, *Carola* and *Pink Delight*, in excellent condition. Messrs. W. Wells and Co., Merstham, obtained second prize with a bright and well-finished stand, having *Dorothy Gordon* and others in good form. Colonel Rideout, Langley, Bucks, came third.

The American Challenge Cup was won by Mr. H. T. Mason, Church Farm Nursery, Hampton, with three grand vases of *White Wonder*, *Dorothy Gordon* and *Gloriosa*, Mr. W. E. Wallace being second and Mr. C. Engelmann third.

Mr. C. Engelmann obtained the Bruton Cup for English novelties, showing *Sunstar*, *Lady Northcliffe* and *Carola*, of splendid form and colour.

Mr. E. Guile, Shortgrove Gardens, Newport, Essex, secured the highest place in the class for twenty-five blooms of *Eochantress* colour with the variety *Lady Meyer*, which also received the silver-gilt medal offered as special prize in the open classes. Mr. W. E. Wallace was second and Colonel Rideout third.

The first prize for twenty-five pink Carnations was secured by Messrs. Stuart Low and Co., Bush Hill Park, with a well-finished vase of *Baroness de Brienne*, Mr. W. E. Wallace coming second and Mr. C. Engelmann third.

Mr. W. E. Wallace achieved first place with the rose pink variety *Gloriosa*; second, Colonel Rideout.

Una Wallace was the premier deep pink shown by Mr. Wallace, Mr. Engelmann following.

The scarlet class was very brilliant in colour. Mr. Wallace taking first with *Scarlet Glow*, Mr. H. T. Mason second with *Beacon*, and Mr. H. J. Dudney of South Road, Erith, third.

Whites were also good, and Mr. H. T. Mason's *White Perfection* was a well-deserved first. Mrs. Collins, Heathfield Nursery, second, and Colonel Rideout third.

The first position in the dark crimson class was secured by Mr. W. E. Wallace with a beautiful vase of *Carola*, which was much admired. Mr. Engelmann taking second place with the same variety.

Mr. Wallace took first in the "fancies" with *Benora*, Messrs. Stuart Low and Co. second, and Colonel Rideout third.

Mikado, shown by Mr. A. F. Dutton, was placed first as being the best vase of any other self-coloured Carnation not included in the above classes. Colonel Rideout obtained second.

Mrs. A. R. Bide, Farnham, secured first prize for a well-arranged basket of Carnations and foliage.

Mr. S. F. Jackson, Danehurst, Epsom, was the successful winner with ladies' sprays, *Captain Wiener*, *Ewell Castle*, Surrey, taking first for six gentlemen's buttonholes, and Mr. W. Heath, The Hylands Gardens, Chelmsford, was placed first for a very pretty hand-basket.

AMATEUR CLASSES.

The beautiful silver-gilt challenge cup presented by Lord Howard de Walden, and offered for a semi-circular group of growing plants, was awarded to C. F. Raphael, Esq. (gardener, Mr. A. Grubb), Porters Park, Shenley, for a well-finished group, having perfect flowers in good condition and colour. Mrs. Bischoffsheim, Warren House, Stanmore, also staged a nice group, and secured second. Mrs. Adair, Adair Place, Englefield Green (gardener, Mr. W. Holder) coming third.

There were two circular tables of cut Carnations arranged for effect, which were very pretty, and the one staged by Sir Randolph L. Baker, Bart. (gardener, Mr. A. E. Usher), Ransdon, Blandford, was very tastefully done and well deserved first prize, Mr. H. Smith, Epping House, Little Berkhamsted, Herts, taking second.

There was keen competition in the table decoration. Sir Randolph Baker was first, and was very closely followed by Mrs. Adair (gardener, Mr. W. Holder).

Sir Randolph Baker took first for six Carnatio plants in bloom, which were in good condition, and Mr. W. Holder secured second.

The Burnett Challenge Cup was won by Sir Randolph Baker with twelve blooms of Burnett's novelties, while Captain Wiener secured first place for six blooms.

Messrs. Wells' gold medal was also secured by Sir Randolph Baker, followed by Lord Burnham, Beaconsfield.

The Dutton prizes, which were very attractive, were offered for twelve blooms of special varieties, the first prize being won by Sir Randolph Baker, Bart., who was followed by P. Ricardo, Esq., The Friars, Old Windsor (gardener, Mr. G. West).

Awards in the non-competitive classes were given as follows, all for Carnations: Mr. C. Engelmann, large gold medal; Messrs. Stuart Low and Co., gold medal; Mr. H. Burnett, large silver-gilt medal; Messrs. W. Lawrence and Son, silver-gilt medal; Messrs. Young and Co., silver-gilt medal; Mr. R. F. Felton, for a table of British novelties, silver-gilt medal; and silver medals to Messrs. W. Cutbush and Son, Highgate, and Mr. G. Lange, Hampton.

HORTICULTURAL CLUB.

A TOUR IN PALESTINE.

ON Tuesday, the 4th inst., after the usual monthly dinner of this club, at which Sir Harry Veitch presided and a large number of members and friends, including many ladies, were present, Mr. Arthur W. Sutton, F.L.S., gave a most interesting lecture, entitled "My Desert Camping Tour to Mount Sinai," illustrated by a hundred splendid photographs taken by him *en route*, and beautifully coloured. Mr. Sutton, who takes a particular interest in the evidence afforded in favour of the accuracy of Biblical records by the actual localities to which they refer, explained at the outset that he was heavily handicapped in this direction by the shortness of the time at his disposal and the difficulty he felt on referring to the views he displayed in not dwelling at too great a length on the many interesting points in this particular connection, which, moreover, he felt were hardly adapted to a general audience. He commenced with a map of the region which he had traversed circuitously for some two hundred miles in company with Dr. Mackinnon, the well-known medical missionary of the Edinburgh Mission in Damascus. The first visit made was to the traditional spot where the passage of the Red Sea was effected, under apparently miraculous conditions, by the Israelites. It would appear, however, that there are three places assigned to this, one of which, to the north, where the water is very narrow and shallow, is considered as the most likely, as an exceptional state of tide and wind might have greatly facilitated the passage on practically normal lines, while the other two involve the traversing of deep water and a much greater distance, which only a colossal miraculous interposition could have rendered possible. The views of the desert were splendid, apparently limitless streaks of barren sand, without a trace of vegetation, alternating with views of brilliantly green oases of Palms, sometimes, thanks to a local supply of water and the generally warm climate, of such luxuriant growth as to be traversable with difficulty. The general temperature varied, however, from 100° in the shade during the day to very near the freezing point at night. The prevailing conditions of sand and the consequent limitation to camels for transport of both travellers and their impedimenta rendered the whole journey a most fatiguing one, camel-riding being so uncomfortable as to compel frequent descents for a rest, and walking being, in its turn, equally exhausting, so that recourse to the camel's back for variety's sake involved no particular charm, and this, with short intervals of rest on the dry, heated plain, and day after day, did but little to recommend the "Promised Land" as a popular resort. In time, however, Mount Hebron and its associated hills of barren granite of brilliant red, interspersed with black and other coloured outcrops, everywhere devoid of even a blade of grass, began to indicate an approach to Mount Sinai, and here, of course, the Biblical records were brought home to the traveller most vividly by the character of the surroundings of these heights, which are regarded as the scene of the most stupendous events. The intervening stretches of sand were here dotted with small bushes, and even one minute flower was discovered by the lecturer. At Sinai there is a monastery, at which both travellers and their cook, guide and camel-drivers had a well-earned and welcome rest prior to the return journey to Suez. A very hearty vote of thanks to Mr. Sutton concluded a most interesting and instructive meeting.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Scottish Horticultural Association was held in the Hall, 5, St. Andrew Square, Edinburgh, on the evening of Tuesday, December 3. There was a satisfactory attendance, presided over by the president, Mr. W. H. Massie, of Messrs. Dicksons and Co., nurserymen. The usual routine business was considered and the nominations of office-bearers for the session of 1913 were made in accordance with the rules. Exhibits were unusually few in number, but this was compensated for by the excellent collection of single-flowered *Chrysanthemums* shown by Mr. W. G. Pirie, gardener to Charles W. Cowan, Esq., Dalhousie Castle, Midlothian. This was a most interesting and beautifully grown exhibit, showing both excellence of variety and good cultivation. There was no set paper for the evening, but the meeting was an "open" one for the discussion of various subjects. It proved an interesting arrangement, as others of the same kind have done, and good discussion arose on such ques-

tions as the effects of grass-land on the coloration of fruit, the effects of galvanised wire, judging of market Leeks, and a number of other subjects comparatively too unimportant for full treatment in a lecture, but of much importance in general practice. The discussion was taken part in by a number of the members present.

THE NEW PRESIDENT.

The new president of the association, as recommended to the annual general meeting, is Mr. David King of the Osborne Nursery, Murrayfield. Mr. King has long taken his share in the work of the association, and has attended faithfully to its interests, furthering its success in every possible way. As coventor of the finance committee he has done excellent work, and as a vice-president he has shown how capable he is of filling the post to be vacated in the usual routine by Mr. W. H. Massie, one of the many able presidents of the Scottish Horticultural Association.

BOURNEMOUTH GARDENERS' ASSOCIATION.

LECTURE ON ROSES.

ON December 3 a very interesting lecture, entitled "Thirty-five Years among Roses," was given by Walter Child Clark, Esq., F.R.H.S., of Michelgrove House, Bournemouth, before the members of the above association. There was a very good attendance, the president (J. H. Ralph Smythe, Esq., J.P.) presiding.

Mr. Clark grows Roses under conditions which would daunt the enthusiasm of hundreds of lovers of these popular flowers. His garden is studded with Pine trees, up the stems of which many climbing Roses are trained. His Rose-beds, which vary in size, number nearly seventy. Interest in the lecture was deepened by the production in colours, on a screen, of fine blooms of good old and new varieties of Roses. These coloured photographs were taken by George G. Hamilton, Esq., F.R.C.S., F.R.H.S., who recently showed them and lectured on the subject at Vincent Square, London. On this occasion he showed lovely views of the New Forest, views of rock gardens and of Orchids.

Mr. Clark remarked on the improved methods of exhibiting Roses in these days, and after referring in detail to many lovely varieties, said that he had found those possessing thick, leathery and glossy leaves were, practically, mildew resisters. The lecturer advised Rose-growers to give their trees two winter dressings, to prevent recurrent attacks of mildew and rust. Owing to the presence of the Pines in his garden, he said it was necessary to constantly remove all fallen needles from the soil. He commenced the cultivation of Roses thirty-five years ago, near Liverpool, by growing six plants in pots, all Teas. Then he had some houses built, in which the Roses, planted out in a central bed and side beds, did very well, owing to the fact that the top glass lights could be removed from the end of June to the end of November, thus ensuring full exposure of the plants after the first flush of Roses was past. The following were some of the varieties shown in true colours on the screen: General Macarthur, Sunburst, Lady Alice Stanley, Lyon, Lady Hillingdon, Mrs. Peter Blair, Hugh Dickson, Frau Karl Druschki, Lady Waterlow, Edward Mawley, Juliet, Rayon d'Or, G. C. Waud, Hiawatha, Carmine Pillar and other climbing varieties. At the close of the lecture there was a very free discussion, in which many members joined, and Mr. Clark replied to a number of questions. Messrs. Pearce, Heath, Evans and Pavey staged some lovely Begonias, *Feros*, *Primulas* and *Calanthes*. Hearty votes of thanks were accorded Mr. Clark, Mr. Hamilton and the president. The public as well as members attended the lecture.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE fifth meeting of the winter session was held at the Institute of Agriculture on Friday the 22nd ult. Mr. C. J. Simpson occupied the chair and about forty members were present. Mr. C. Wakely of the Agricultural Institute gave an interesting lecture on "Pot Plants and Potting." In the course of his remarks the lecturer covered a good deal of ground, and dealt with his subject in his usual clear and concise manner. In order to make his lecture of practical value, Mr. Wakely brought some specimens of plants and potting material, such as peat, loam and leaf-mould. At the conclusion of the discussion a hearty vote of thanks was accorded Mr. Wakely for his instructive lecture.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

ON Wednesday evening, November 27, the committee arranged a couple of competitions in vase decoration, when prizes were awarded for the best arrangements. There were thirteen entries, and the whole of the results were of a very high order, reflecting great credit on the competitors. The prize-winners in the head-gardeners' and foremen's class were: 1, Mr. A. Hirsted, Old Vicarage Gardens, Shiplake; 2, Mr. W. H. Scott, Hermitage Gardens, Twyford; 3, Mr. H. Atlesey, Wargrave House Gardens; and in the class for journeymen: 1, Mr. Bristow, Scarlets Gardens, Hare Hatch; 2, Mr. R. Baker, Park Place Gardens; 3, Mr. Dancer, Scarlets Gardens, Hare Hatch. Votes of thanks were accorded the judges, Messrs. Hall, Pope and Stephens, who had a most difficult task to perform. The flowers used in the competitions were sent to the Royal Berks Hospital the following morning. Two new members were elected, making a total of twenty-two this session.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Lenten Roses Flowering Early.—From several sources we learn that the Lenten Rose, *Helleborus orientalis*, is flowering with the Christmas Rose, *H. niger*. This is unusual, as the Lenten Rose does not generally flower until early spring. Owing to the mild weather, Snowdrops, Double Daisies and Polyanthus are all blossoming freely in gardens around London.

Wallflower Early Paris.—One of the most interesting plants in our outdoor garden just now is the Early Paris Wallflower. Seeds were sown in the open towards the end of April, and the plants, after being well thinned, commenced to flower towards the end of June. Since then it has always been possible to gather a posy of fragrant blossoms, and now, the middle of December, there is quite a goodly array. In addition to the ordinary yellow-flowered variety, there is one with rich brown blossoms. For their fragrance at this season, these Wallflowers are well worth growing.

The Golden and Red Barked Willows.—On several occasions of late very effective plantations have been noted of these two Willows. In some instances they were in wide areas, grown for commercial purposes, while in others they had been planted in the vicinity of water for landscape effect. In each case the result was very pretty, especially on a sunny day. Anyone who possesses a lake or pond might very well introduce a mass or two of these Willows, which are also very useful for planting about the banks of rivers or brooks. It must be remembered, however, that the best colour is only produced when the plants are cut down annually, for long, quickly-grown branches are always the brightest.

A Useful Winter Shrub.—The Himalayan Cotoneaster, known as *C. rotundifolia*, is worth planting extensively in gardens where showy fruiting shrubs are required, because birds do not interfere with the fruits as they do with those of other kinds. It is no uncommon event for the berries to hang throughout winter and early spring. Although a deciduous species in most places, it may retain its leaves throughout winter in a mild climate, and even about London they rarely fall before Christmas. Growing 4 feet to 4½ feet high, it is distinguished by its round, box-like leaves and rich red fruits, which appear with the greatest freedom from all parts of the branches. It grows quite well in any good garden soil.

A Pretty Greenhouse Climber.—Anyone who is in search of an uncommon climber for the greenhouse might with advantage choose *Heliophila scandens*, for it is at the same time a free-growing and a free-flowering plant, while it blossoms during late autumn and winter. A native of South Africa, it belongs to the Cruciferae, having the common

Wallflower as one of its relatives. Its long, slender branches are of a sub-shrubby character and attain a length of 15 feet or 20 feet, becoming during the growing period tangled together to form a mass of considerable size if care is not taken to regulate the shoots. The Wallflower-like leaves are dark green and persistent, and against them the freely-produced white blossoms are contrasted with considerable effect. A sunny position is essential to success, while the roots revel in loamy soil.

Ferns in Glass Bottles.—In the current issue of the *British Fern Gazette* Mr. C. T. Druey publishes some interesting particulars about Ferns in glass bottles. We quote the following: "We have still in our fernery a wide-mouthed white glass pickle jar, into which, at least eight years ago, we introduced a tiny Hart's-tongue, simply laid upon clean washed damp silver sand of little more than an inch in depth. The month of the jar was closed by a glass stopper rimmed with rubber, and this was tied down with copper wire to prevent removal. The Hart's-tongue grew until it filled the jar and reached the stopper, renewing its fronds for several seasons; a mass of confervoid growth had meanwhile covered the sand, and eventually two plants of *Lastrea Filix Mas*, doubtless arising from stray spores on the Hart's-tongue, appeared. The Hart's-tongue then died, but both the *Lastreas* are still alive, though small, despite the fact that absolutely no fresh water has been admitted to the jar from the day of its installation and the stopper is quite air-tight."

A Useful Rambling Plant (*Polygonum baldschuanicum*).—One of the most satisfactory ways to grow this plant is to place it in a pocket of good loamy soil in a sunny position at the foot of a loose-growing Holly or other evergreen tree, over which it may ramble without hindrance, for it is only when left to its own devices and allowed to grow in a perfectly free manner that the best results are obtained. Growing in such a way it rarely fails to produce an abundant crop of flowers each year, which are well set off by the evergreen foliage of the tree over which it is growing. Some people complain that their plants do not flower freely. There may be several causes for this. The plants may be too young, for, until the older branches are well developed, prolific flowering does not take place. Another cause of lack of flowers is the provision of too generous a root-run in rich soil, while a third cause is shade. As a rule, however, the plant may be depended on to give satisfaction, and the greatest difficulty people experience is in its propagation. It may, of course, be raised from seeds, but both cuttings and layers are somewhat erratic in their behaviour. Another effective use for the plant was noted some time ago, the whole of the west wall of a red-brick house being covered with it, the white flowers and fruit being very conspicuous against the wall.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Billbergia liboniana.—This good winter-flowering stove plant is not too common now, but it is worth notice at the present time, and I saw a nice plant the other day. It is about a foot high, and has a dense rosette of rigid leaves, with flowers of a wondrously fine colouring. The inner segments are purple and white, and the exterior ones are of a bright coral red, the whole being one of the most effective plants of the season. The plant had been removed from the stove to an intermediate house to prolong the bloom, and was grown in loam, leaf-mould and peat with some sand, the orthodox compost for most of the members of the genus.—A. M. D.

The Golden-leaved Chestnut (*Castanopsis chrysophylla*).—This is an interesting and useful evergreen shrub closely allied to the Sweet or Spanish Chestnut. It is one of those choice subjects for those who collect interesting and rare plants. Coming to us from California and Oregon, the selection of a sheltered spot when planting is desirable. At Kew several good specimens are growing in the Heath-beds near the Pagoda. At first sight the evergreen foliage and general character of the plants when no fruits are visible suggest the Evergreen or Holm Oak. Closer inspection, however, shows the rich golden colour of the under sides of the leaves; hence the name of the Golden-leaved Chestnut. Its affinity with the Spanish or Sweet Chestnut is revealed in the fruits, which, though smaller, are similarly spiny in character. An interesting fact is that, like some of the Oaks, the fruits take two seasons to mature. In early July this year, when the plants were freely clothed with the showy male catkins, the crop of fruits from the previous season's flowering was very noticeable. The fruits ripen in September, and should be sown a few days after gathering.

***Lilium tigrinum Fortunei*.**—This is one of the very best of the late-flowering Lilies for the open border, where it makes a goodly show. Immense bulbs of it are sent here every year from Japan in considerable quantities, and these push up a stout, erect stem that will reach a height of 6 feet or even more. The leaves are very numerous, and the entire plant—stems, leaves, flower-stalks and unopened buds—are thickly clothed with whitish tomentum. The flowers in the finest examples are borne in a large open, pyramidal-shaped head. In colour they are of a somewhat lighter tone than the other varieties of the Tiger Lily. For its successful culture no elaborate preparation of the soil is necessary, as in a border of fairly open loam it will succeed perfectly. It is necessary to plant the very large bulbs deeper than those of many other Lilies, a covering of about eight inches of soil over the top of the bulb being very suitable. The other Tiger Lilies are, as a rule, over before this is at its best. Unlike several other members of the genus, the Tiger Lily in all its varieties can be depended upon to flower well the first season after planting, but for growing in pots by far the best is the variety *splendens*, or *Leopoldii* as it is often called. This has very dark, smooth stems

and brightly-coloured flowers, with larger spots than the others. Under pot culture it retains its leaves well, which, as a rule, cannot be said of the rest.

***Primula malacoides* in Winter.**—Nothing has given me greater pleasure lately, both in the greenhouse and in a light and sunny window of the dwelling-house, than this comparatively new Chinese species of *Primula*. It was not so very long since we hailed it as a novelty, and now it is very widely distributed. This is to a great extent owing to its own intrinsic beauty and simple cultural requirements, also to the fact that seed ripens in quantity, and large numbers of plants can in this way be propagated from a single specimen. It has already become established as a market plant. With the exception of the white-flowered variety, I have seen no great divergence from the normal kind, the blossoms of which are of a pleasing shade of lilac. Judging, however, by the changes that have taken place in *Primula sinensis* under cultivation, and the more recent

FRUITING SPRAY OF THE GOLDEN-LEAVED CHESTNUT, A CHOICE EVERGREEN SHRUB FROM CALIFORNIA.

example of *Primula obconica*, we may, within the next generation, see many widely diverse forms of *Primula malacoides*. While on the subject of *Primulas*, I may mention that a recent note on *Primula Forbesii* pleased me much.—H. P.

A Winter-flowering Broom.—*Cytisus filipes*, a native of the Island of Tenerife, is one of the most graceful of all shrubby greenhouse plants. Another desirable feature is that its flowers are borne during the winter months. From the semi-pendulous nature of its branches, this Broom is sometimes grown as standards, being for this purpose grafted on to naked stems of the *Laburnum*. From my own point of view it is, I think, the more pleasing when the plants are allowed to grow by securing the leading shoot to an upright stick, and allowing the branches to dispose themselves in a loose and informal fashion. In this way it forms what has been described as a living fountain of

slender, bright green branches, with very few leaves, as in other members of the Broom family. The flowers, which are borne for a considerable distance along the shoots, are white, and of them a succession is kept up for some time. This Tenerife Broom may be increased by grafting on the *Laburnum*, while cuttings may be struck, but it is not readily propagated in this way. Seeds are, however, often ripened, and from these young plants can be easily raised. True, they will not flower in quite such a small state as those from cuttings, but they form more handsome specimens.—H.

Sweet-scented Verbena.—I was much interested in the reference to this *Verbena* (*Aloysia citrodora*), page 610, issue December 7. Of fragrant-leaved plants it is in the front rank. For a number of years it was my duty to fill a large bed with sweet-scented plants, either of flower or foliage, and I used a number of old plants of this *Verbena* among others. Several of the specimens were 4 feet high and as wide. They were allowed to grow at will during the summer, pruned hard back late in autumn, and stored in a coolinery through the winter, receiving one or two waterings. In spring new shoots grew again, and the plants were, in due course, transferred to the bed. Every spring I propagated plants freely, selecting young shoots 4 inches long and inserting them in almost pure sand in a hotbed.—B.

What to do with Frozen Plants.—Your leading note in the issue for December 7 is very timely. It is pithy and to the point, and if acted upon, in case of frost reaching any plants, the owners would find how very useful the advice was. I only wish here to give an instance of the efficacy of the treatment recommended. Some years ago I had a large frameful of the Castor Oil Plant (*Ricinus Gibsonii*) badly frozen early in the spring. The attendant had opened the frame, and the sun was just reaching them when I passed. The leaves all drooped like so many damp cloths round the main stems of the plants. I at once broke the ice in a cistern near and syringed the plants with the ice-cold water, and having closed the lights and put on several mats, waited three or four days until the frost had gone before again opening the frame. All the leaves had regained their normal positions, and only one had two brown patches on it.—G. G.

The Fan Palm in Scotland.—The Fan Palm is much harder than many can understand, and there are to be found a goodly number of plants in Scottish gardens in different parts of the country. They cannot be said, as a whole, to look too happy, but this is not due to any want of hardiness when planted in suitable situations, but rather to the effects of wind, which one finds is very destructive to the beauty of the plants. It is many years since the writer came upon a good plant of the Fan Palm in an East Coast garden, and since that time he has seen a number in different parts of Scotland. It is generally best when sheltered by other trees or shrubs, as where there are walls there are often eddies and gusts of wind which prove injurious. That it is fairly hardy may be seen when I state that it is to be met with in a garden well up Corstorphine Hill, near Edinburgh, where the place is subject to very high winds. In a good many gardens in the West the Fan Palm is also to be met with.—A. M. D.

Winter Aconites Flowering Early.—The first Winter Aconite of 1912 opened on January 1; the first of 1913—if I may use the expression—opened on December 8, 1912. The latter date is the earliest I have ever found it in flower in Suffolk.—T. H. DIPNALL.

Fragrant Chrysanthemums.—That old decorative variety Bronze Phœbus has a delightful scent, and one of the market-growers at Davidson's Mains (Mr. Alexander Porter) continues to grow it for the Edinburgh market partly on that account.—CHARLES COMFORT.

Fatsia japonica.—Is it not rather uncommon to see good-sized specimens of this subject growing outside and standing the winter in bracing districts? This locality—Highgate, North London—is the first and only place I have come across them so grown. The bulk of the plants I have noticed in gardens have been leggy, with only a few leaves clothing the top portions of the stems, and these were never left to face the winter. Further South I am aware they are to be found always in the open; perhaps they are hardier than is usually believed. Anyhow, there are here in two different gardens two good plants of about four and a-half feet high and 3 feet to 4 feet across, and very healthy in appearance. Peculiarly attractive just now is the unfolding of their burr-like headed inflorescence. This plant is better known to some as *Aralia Sieboldi*.—C. T.

A Useful Winter-flowering Orchid.—*Zygopetalum Mackayii* is a fine Orchid for an amateur's Orchid-house, where the temperature does not fall below 50° Fahr. The scapes are produced during the winter months and the flowers are a yellowish green, while the broad lip is white, streaked and spotted with violet purple. A few weeks after the spikes are removed any repotting may be done, using a mixture of the best fibrous loam and peat, with a few finely-crushed potsherds to render the whole porous. When in good health, *Zygopetalum Mackayii* is very vigorous, and requires ample pot room to get the best results. Keep the plants moist throughout the year and a careful watch for thrip, which is extremely fond of the new growth. There are many home-raised seedlings on the market equal to imported specimens in regard to colour, but possessing a more robust constitution, and for this reason an amateur should always secure the home-raised seedlings.—S.

"Carnation Notes" in "The Garden."—May I express appreciation, before the year closes, of the increased attention—the more regular articles—which has been devoted to that most popular flower, the Carnation? True, the special notes referred to have dealt with the border section only, but there have also been articles on the Malmaison and perpetual types. What other plant can furnish us with three such valuable divisions—the Malmaison, the perpetual and the border—and each giving us a good measure of beauty and fragrance? By the way, I believe it is thought by many Carnation-growers that the outdoor kind of Carnation for the future will be a hybrid between the last two. It would be most interesting if any reader of THE GARDEN, having experimented with plants so obtained, will give to other readers the benefit of his results.—C. T.

FORTHCOMING EVENTS.

December 30.—Hereford Fruit Show (two days).
January 7, 1913.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster, S.W.

GARDENING ACROSTICS.

AS announced last week, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. In the event of more than one competitor sending in eight correct solutions, the prize-money will be divided as follows: If two competitors are successful, the first and second prizes will be added together and then divided; if three or more, the whole of the money will be added together and divided. The second and third prizes will be similarly dealt with, should similar circumstances arise in regard to them. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize-winners in our issue of February 15, 1913. In all cases the Editor's decision must be final. The solution to Acrostic No. 1, which appeared last week, will be published, together with a list of those who have correctly solved it, next week, and the solution to No. 2, which is printed below, will be published in our issue dated January 4, 1913. For full rules governing the competition readers are referred to page 623 of our issue for last week.

DOUBLE ACROSTIC No. 2.

A famous Victorian gardener, editor and designer. The first letters give his Christian name and the final ones his surname.

1. The initials of a celebrated Horticulturist and Botanist of the early half of the seventeenth century.
2. Royal and Saintly, I am alone in my glory. I might be a flower, but I am not.
3. I look like a pistil in the middle of a large white petal. What would a botanist call me?
4. Milder than an onion—pedantically spelt.
5. A disease-proof tuber would be worth far more than its weight in gold. Of what?
6. A part of London celebrated two hundred years ago for its vineyard.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than December 28. Mark the envelope "Acrostic" on the upper left-hand corner.

CULTURAL HINTS ON NEW AND RARE PLANTS.

ALPINES.

(Continued from page 623.)

Primula Winterei.—This proved quite the idol of alpine plant-lovers when first shown, the mauve, white-centred flowers appearing in a striking setting of powdery leafage. The plant is Himalayan, and very charming when in flower. Seeds should be carefully preserved, and the plant raised freely. It prefers a rich, sandy soil. Flowers in April and May.

Primula bulleyana.—Here is a plant to join forces with *Anemone Allenii* in the cool and moist places of the garden in rich soils. No praise is too strong for it. The flowers are of golden orange hue, the buds reddish. It comes from China. The plant seeds freely, and is easily raised if the seeds are sown soon after being harvested. Hardy, free and vigorous, this plant of many merits should be grown by all. There is no other *Primula* like it.

Primula littoniana.—A remarkable plant in every way; novel, beautiful and striking, and

certainly one of the most effective when grouped. The flowers are arranged in a spike raceme, and in the distance are not unlike an *Orchis*, save for the red colour at the tip of the spike. The plant grows freely in cool, moist soils, and is easily increased by means of seeds. The established plants may be put out at any time. Of Chinese origin.

Sedum pilosum.—This is a very distinct and pretty member of the genus, with woolly, almost *Sempervivum*-like rosettes of leaves $1\frac{1}{2}$ inches across. The flowers are whitish or pale lilac. Prefers a dry chink at the base of a rock. Grows freely in grit, soil and old mortar rubble. Easily raised from seeds.

Silene Hookeri.—In the rock garden exhibits at the International Show in May last many lovers of alpine plants made the acquaintance of this for the first time. The flowers are rose pink and much lacerated. For a sunny chink in the rock garden it will prove quite a gem. Best raised from seeds. Succeeds in loamy soil perfectly drained. It is Californian.

Patrinia palmata.—A novelty of distinction and merit from the Japanese Alps. The shortly-spurred flowers are yellow profusely borne on branched stems nearly a foot high. The leaf-tuft is a miniature, practically, of some *Heucheras*, and when established will doubtless increase quite freely by means of division. A quite hardy, free-growing subject.

Lewisia Cotyledon.—Should this species with *L. Howellii* prove to be perfectly hardy in British gardens, they will constitute two of the most interesting alpine a rock garden could contain. Both have rosettes of fleshy leaves, the former having golden yellow, crimson-striped flowers; the latter, rose-coloured flowers. The plants are sun-lovers, and should be given a warm position. For the sake of safety protection is suggested. They are Californian.

(To be continued.)

THE MAKING OF GARDEN ROADS AND PATHS.

THE construction of roads and paths is a very important item in the laying out of a garden, for it depends largely on whether they are made well or badly as to whether they can be used or not in wet weather. Of the many points to consider in connection with the work, one of the most important is drainage. When the ground is naturally well drained, the work is simplified, for there is little necessity for the construction of an elaborate drainage system. Surface water can be easily carried away by catchpits made here and there along the margins, the size and depth being regulated according to requirements. But when the ground is naturally heavy and badly drained, it is highly important that a good service of agricultural drains should be laid to prevent the path from becoming waterlogged. In such a case the ground should be excavated to the required depth and be left 2 inches or 3 inches higher in the middle than at the sides. A drain can then be formed along each side, with branches 20 feet or 25 feet apart falling each way from the middle. Connections must also be made between the surface and the side drains for the purpose of carrying surface water away. This is really more important when the road or path is to be used for vehicular traffic than when it is to be wholly for the use of pedestrians.

for if such a road is not well drained, it is impossible to keep it in good condition.

The contour of the ground is another item which has an important bearing upon the construction of roads and paths. When the natural ground is moderately level, or has a slight general slope, the work is more simple than when undulating ground or land with a rapid fall has to be dealt with, for in the one case it may be necessary to reduce hillocks and fill up depressions both for appearance and to ease the road for traffic, while in the latter case steps must be taken to make the road as easy as possible to climb, and also to provide against its being badly washed by heavy storms. When removing hillocks and filling little depressions, care must be taken to arrange the sides of the road in such a manner that they look perfectly natural; thus it may be necessary to regulate the ground for 20 feet or 30 feet back in order to make it approach the road more or less in the form of the sides of a valley. Should it be impossible to alter all hard lines, then banks of shrubs, judiciously placed, may be made to mask the defects. The gradient

A path which has been excavated 6 inches or 8 inches deep should be drained, if necessary, and have 3 inches of hard core, stone or brick rubble placed over the bottom. On this place from 1 inch to 2 inches of coarse clinkers, and ram them down until a level surface is formed. Then proceed to fill up with whatever material has been selected for the surface. As a rule, nothing beats a good binding yellow gravel which has not been screened too finely. This must be spread and well rolled while moist, otherwise it will not set. There are two periods when gravel is objectionable. One is the early days of a thaw after a frosty period, and the other is a light rain after a dry period. At both these times the surface is wet and soft and the lower part dry and hard, consequently the upper part is lifted by the feet or by wheels. There is no help for it, and nothing can be done to remedy it except keeping off the path while it is in either of these conditions. For this reason it is often desirable to lay asphalt paths in small gardens where the paths are in everyday use, but when this material can be avoided, avoid it by all means.

DIAGRAMS TO SHOW THE CONSTRUCTION OF GARDEN PATHS.

A.—Plan of drains in bed of path: 1, bed of path; 2, 2, side drains; 3, 3, branch drains. B.—Section of path showing drains: 4, 4, catchpits at sides of path; 5, 5, section of side drains showing connections with surface and branch drains; 6, branch drains in bed of path; 7, rough material; 8, the finished rounded surface of the path. No. 9 shows a paved channel, and No. 10 section of pipe channel.

of a steep road or path may be eased considerably by using good bold curves; but when the road is for vehicular traffic, the curves must have really good sweeps, for sharp turns are both awkward and dangerous. Then, to stop the wash of water flowing rapidly down and carrying gravel with it, it is a good plan to have large houlders placed in the gutters every 20 yards or 25 yards immediately below a drain, while in some cases it may even be advisable to pave the gulleys with setts or to lay glazed earthenware pipes, cut in longitudinal section, along the sides.

The depth to which it is necessary to excavate a path or road depends entirely on the purpose for which it is to be used. A path which is simply for use by pedestrians may be from 6 inches to 8 inches in depth, while one for light vehicular traffic should be from 9 inches to 12 inches, and if heavy traffic is anticipated, from 12 inches to 18 inches; but such roads are, as a rule, best paved, that is, when they are destined for service roads for gardens and back premises, rather than for carriage drives.

Loose gravel or granite chips are sometimes used in preference to a binding gravel, but these are not very satisfactory, especially when the path is destined for heavy use, for the loose chips soon become filled with soil and other dirt. By rolling on every possible occasion, a well-made gravel path keeps in good condition, and there is nothing to beat it for appearance. Carriage drives and roads must be given from 6 inches to 12 inches of hard core, according to depth, and over this, flints or broken granite should be placed to bring the road within 2 inches of the surface. Make it as firm and level as possible, then cover with gravel and roll well. Such a road will stand a considerable amount of wear, providing wheel marks are regularly raked over and the surface frequently rolled. A fertile source of injury to roads is the heavy shade of trees, which does not allow the surface to dry, and by their leaves falling and not being regularly cleaned up. Foreign matter of any description must be removed from the surface at once if the road is to remain good. Since the advent of motors, some people have taken to tar

spraying the surface of carriage drives. Roads so treated wear well, but are less pleasant to the eye than those surfaced with gravel.

For temporary roads there is no need to go to the same trouble or expense as is necessary for permanent ones, and excellent roads, capable of carrying a lot of heavy traffic, may be constructed of old railway sleepers, which may often be obtained for 9d. or 1s. each from the railway companies. The life of these old sleepers may be anything from five to twelve years, therefore a good deal may be said in favour of their use.

THE FRUIT GARDEN.

THE WINTER SPRAYING OF FRUIT TREES.

THE spraying of fruit trees is fast finding favour with those who but a short time ago were quite sceptical as to any advantage to be derived from the work. As to the efficacy or otherwise, one has but to remember how much has been done of late by fruit-growers for profit in the spraying of their trees, and one may rest assured that these men would not waste valuable time and material if the trees were not benefited in some way. At one time I was inclined to doubt the wisdom of spraying the trees for the many insect pests and diseases that are now recognised as being injurious in some form or other; but having experienced several bad attacks of Apple scab, I was tempted to try remedial measures, and I am pleased to say, with remarkable effect, so that I am now a strong convert to the practice of systematic spraying. Perhaps my recent sceptical feeling was caused by being some years ago wrongly advised in the use of a certain spray fluid, so much so that I lost all the leaves from many trees, which made me extra careful. No doubt the yearly practice of many years ago of coating the stems of orchard trees with quicklime by the aid of an ordinary whitewash brush led up to the invention of sprayers, which have gradually been improved, so that now there is not the slightest difficulty in coating the trees thoroughly with whatever insecticide is required.

Advantages of Spraying.—"What are the advantages derived from spraying?" the sceptic will naturally ask. First, the removal of moss and lichen from the branches, which must do much harm to the growth of the tree. The necessary vigour of trees that are coated with a full crop of moss, and at times with lichen fully 3 inches in length, must be impaired. Even Gooseberry trees which are susceptible to the growth of moss on the branches and main stems never grow vigorously, and in consequence cannot produce crops of fruit equal to what may be naturally expected from them. In the same way are Currant, Apple, Pear and Plum trees affected.

Secondly, Apple scab (*Fusicladium dentriticum*) may be quite overcome by the aid of spraying, and if this alone can be achieved, then the work of spraying is at once repaid. What is worse to the Apple-grower, market or otherwise, than to find almost the whole of the fruit, by the time it is the size of a Walnut, full of disfiguring specks and rust, and which later on contracts, or, in other words, its presence kills the skin of the Apple, preventing any expansion and, as the fruit swells, causing the skin to crack, so spoiling entirely all the fruit affected? Some varieties are more liable to Apple scab than others; for instance, Lord Grosvenor, Warner's King and Stirling Castle

are very susceptible to this fungus disease, which is obstinate in its attack. It can be quite eradicated by assiduous attention.

Thirdly, the Apple-sucker (*Psylla Mali*), Codlin moth, winter moth, Gooseberry sawfly and lackey moth, as well as attacks of aphides, green and black, can all be got rid of by spraying if done in an intelligent manner and with the right material. That great enemy of outdoor Peach culture—blister, or leaf-curl—is caused by fungus, which appears when the young growth is checked by cold winds, and can be removed by spray fluids. Enough has been said to show the value of spraying; the next point is how to efficiently carry out the work for the various remedies.

The Best Spraying Apparatus.—The first point to consider is the form of sprayer to use for the various washes required. In the case of a few trees, such as the amateur may require, an Abol syringe with various sizes of nozzles will suffice. For an ordinary private garden a knapsack sprayer is the best means of carrying out the work. What is required is an efficient article that is the easiest manipulated. I can recommend most strongly the "Holder" pneumatic sprayer. This sprayer has a holding capacity for two and a-half gallons of liquid with a self-contained pump. Within a couple of minutes a pressure of 70 lb. is obtained, with which the whole of the liquid is sprayed over the trees in a fine, mist-like spray without further pumping to a height of 15 feet, according to the length of hose and guiding-tube. With this sprayer both hands are left free, which is such an improvement over those sprayers that require continuous pumping. The container is made of solid welded copper to prevent corrosion. The machine will apply lime or anything in the way of spray fluid.

The Four Oaks Spraying Company make an excellent knapsack sprayer, invented by Mr. W. H. Lawrance, Inspector under Destructive Insects and Pests Orders in the county of Hants, and who has had considerable experience in spraying, both winter and summer. The special feature of this machine is the remarkable ease of working; the handle comes over the shoulder, and the working action is very easy and non-tiring. All classes of chemicals can be used with this machine, as it has a double container. In the case of those requiring added power where a large area has to be sprayed, Messrs. Drake and Fletcher make an excellent machine, which they name the "Mistifier," made quite narrow for passing up and down the rows of trees. What they term their "M. M. O." machine holds thirty gallons of liquid, and has two sprayers, which are worked by two men, one on each side of the machine, if necessary. One person continually pumps the liquid to the sprayers, and with the machine kept regularly supplied with spraying fluid, much work can be got over during the day. Naturally, the firm have larger machines of the same type holding up to sixty gallons of liquid.

These sprayers, including the Knapsack Patent, can be used for Potato-spraying equally well, and it is surprising what a large area one man can get over in a short time when fully accustomed to the work. In passing, I might say that dry spraying is much preferred by many for Potatoes, as being more economically applied. This part I will deal with fully later on.

The Best Winter Spraying Fluid.—Like all other details in connection with the garden, there are many recipes for the cleansing of trees from moss, lichen and insect pests. One of the most efficacious, safe and easily applied is quicklime. Not only does lime cleanse the trees from moss and other extraneous growth, but it is valuable as a stimulant to crops growing underneath the trees, as well as being beneficial to the trees themselves, especially where lime is deficient in the soil. For these reasons lime is largely employed by fruit-

the liquid passes when filling the sprayer. In the case of the "Holder" machine the necessary pneumatic pressure is steadily pumped up, and the machine is then ready for use. The operator, with the sprayer on his back, occasionally gives the machine a tilt to keep the lime well mixed, so that it is sprayed evenly on to the trees. Various lengths of hose and lances are required, according to the height of the trees to be sprayed. With various brass unions the one sprayer can be employed when required. In applying the liquid to the trees, the operator will soon learn how much is required to coat every portion. Each grower has his particular time to start lime-spraying. Some begin at the end of November, others not until the buds are bursting in spring, some even later than that. In my case I commenced to lime-spray the Apple trees on April 16 this year. At that time the flower-buds were quite prominent. No harm accrued; indeed, I tested some trees with the blossoms fully expanded, and with satisfactory results.

Apart from lime there are many other insecticides which may be employed, with good results; for instance, the Woburn wash, as it is termed. Bentley's, too, make a capital powder for the cleansing of trees from moss and lichen, and really well it answers. Messrs. Strawson prepare a mixture known as Strawsonite, which has a good effect upon the trees during the winter. Then there are the various sprayings required for the usual spring insect pests, such as the psylla, aphid, &c., which I purpose dealing with later on.

Swanmore Park. E. MOLYNEUX.

A BEAUTIFUL ALPINE, ASPERULA HIRTA, IN THE GARDENS OF THE
LUSANNE UNIVERSITY AT PONT DE NANT.

ROCK AND WATER GARDEN.

A DAINTY WOODRUFF. (*ASPERULA HIRTA*.)

THIS tiny Woodruff is a dainty little alpine, and seems to appreciate being planted in a crevice, where its dwarf growth can spread out fanwise over the rocks, so securing the fullest amount of sunlight, yet always having its roots in a moist medium behind the large blocks

of stone. The flowers, which are trumpet-shaped, are generally white, or faintest pink, in colour; but when they receive the fullest amount of light, the pink tint is more pronounced. Recently, while visiting the garden belonging to the Lausanne University at Pont de Nant, above Bex, at the eastern end of the Lake of Geneva, I noticed this little Woodruff growing very vigorously, and always in the position indicated above. Another member of this same family, which there flourished amazingly, was *Asperula nitida* (or *A. Gussonii*). While not one of the easiest of alpine plants to grow in our low-land gardens, it seemed to revel in the almost natural conditions at Pont de Nant, where, during the winter, a snowy thick mantle ensures a complete rest to all the plants in the garden, which is situated at an altitude of 4,110 feet. REGINALD A. MALBY.

growers. The best hard stone lime is necessary, not that which is soft, as is sometimes the case when made from some kinds of chalk. Eighty-six pounds of lime is sufficient for fifty gallons of water. This amount of lime should be put into a galvanised vessel, adding a small quantity of water to start the lime dissolving. As this proceeds add more water, constantly stirring the whole with a shovel, never allowing it to become quite dry nor making it too wet. Just keep it sufficiently thin to stir and become regularly dissolved. When this has taken place, strain the whole through a fine sieve into another vessel to remove any small portions that may tend to choke the pumps or spray nozzles; but when the lime is good this seldom happens. Add water sufficient for the quantity noted. Each sprayer is fitted with a strainer, through which

ROCK GARDENS IN THE MAKING.

(Continued from page 626.)

The Last Phase.—In all gardening operations planting follows "making" as night follows day. In previous chapters I have touched on some of the more important phases of rock gardening chiefly from the amateur's point of view. No attempt, however, has been made to make it exhaustive or complete. To have done so would have required a volume of considerable size; indeed, I know of no work wherein every phase of rock gardening has been discussed, or that very considerable improvement were not possible of introduction. What I have endeavoured to do, so far as the ground has been covered, is to point the way, and if so much has been accomplished helpfully to those for whom it was intended, I shall have played my part. If not—if I have not dived into the innermost recesses, crevices, cracks, crannies or fissures of some individual case or circumstance—there is no occasion for those who

gardens were of the miniature type, only possible of inspection from the front, there would be some excuse for the, wrong to which I refer. The same thing, however, is done in not a few instances where rock step or path has been arranged to permit the owner to wander at will, the result generally a very incongruous whole. Deftly-arranged rock steps or paths, while permitting a close inspection of all the plants, also present a dual possibility to the planter; and ornamentation of such a kind—rock bristling with vegetable-life at every turn—is rock gardening in its truest form; to the intelligent planter ideal. It is in this connection, too, that I must again ask my readers to refer to the coloured plate given of

The Friar Park Rock Garden in the issue dated October 26, 1912. The teaching value of the coloured plate is great in the direction indicated. I do not say the picture is perfect, however, from the planter's point of view. It is too embracing; no single picture could possibly be perfect; that type of perfection which the rock garden itself

area of ground. These are the things that not only make for success; they are those which furnish and garnish, wedding plant to rock and rock to plant as though the twain were made for each other's company and were inseparable. Evidences of such thoughtful work as this occur in the immediate forefront of the coloured picture, where a trickling stream of purple Aubrietia forming a shallow pool lower down invests its surroundings with great charm. A little higher up, on the right, a flood of colour is contributed by some of the free-flowering Dianthi, a genus rich in colour and variable in habit. The larger-growing of these alpine Pinks are useful in many ways, though most of all, perhaps, in the colour effect of their massed colonies, good at 50 feet or 100 feet away, and in the glaucous grey of their leaf-tufts in autumn and winter. The fine group of Alpine Pinks shown in the coloured plate already referred to is

Very Suggestive of Nature's Handiwork, and as such of much teaching value to the planter.

There is no formality, no abrupt terminating of the group; on the contrary, there is abundant evidence of the plant effacing rock, tumbling from ledge to ledge, pressing itself into every crack or crevice as it proceeds, reproducing, apparently, in miniature the flowery tufts and effects from which they sprung. It is as though seeds or shoots separated from the parent group had made for themselves a home, and, pressing onward and downward, bejewelled the rock as in Nature's own inimitable way. The group itself at Friar Park is, as may be imagined, of considerable extent, and a great joy to its owner and all who see it when in flower. In its naturalness and suggestiveness it is the most perfect bit of planting that I know, a masterpiece of the art which conceals art. Hence it is worthy of study and of emulation, not of a slavish kind, but of the principle embodied therein, and which is applicable to other plants besides. E. H. JENKINS.

*(To be concluded.)***A DWARF EVENING PRIMROSE.***(EITHERA ARENDsii.)*

This is a pretty plant for a sunny, well-drained bank, or ledge of the rock garden. Running freely at the

A DWARF EVENING PRIMROSE, (EITHERA ARENDsii), IN MR. E. A. BOWLES' ROCK GARDEN.

all unwittingly have apparently been ignored to flounder in the dark; the columns of THE GARDEN are as free to them as of yore, and with their grievance or their requirements duly set forth, the case will receive immediate attention. Hence no apology is made for shortcomings or incompleteness, since these very things will of a surety exist in that phase of the subject with which I am now about to deal. In discussing the

Planting of the Rock Garden, one cannot but direct attention to one of the commonest of errors and the way the work is done, despite intelligence, travel and the great teachings of Nature herself. We plant the choicest things usually low down; the bolder things with trees and shrubs on the higher parts. In Nature the exact opposite is the case; the nearer we approach the glacier or the field of the eternal snows, the dwarfer and more diminutive does vegetation become, till presently it virtually ceases altogether. It may be that in lowland gardens we so plant as a matter of convenience, and if all rock

demonstrates so well at every turn. Perfection, indeed, from our present standpoint could only have been attained by a great series of pictures, fifty or a hundred such, showing in more or less detail the individual subject now in sweet communion with, or at other times almost entirely effacing, rock, than which there is no greater lesson to teach. Such things, indeed, should be regarded as fundamental, first principles, as it were, to all who would see their rock gardens glittering with plant-life, instead of so much coarseness and so much of uncompromising rock, serving little or no useful purpose.

To Achieve all This, or, indeed, any considerable proportion of it, the planter must know his plants, must appreciate their habit and full development, must know of their likes and dislikes, their preferences for sun or shade, must be able to differentiate between the lover of crevice or fissure and that other type spreading laterally and more mat-rooting, which finds a congenial abiding-place on a larger

root and flowering on young plants from these runners, it soon covers a good space with flowers of a singularly delicate rose pink, much the shade of a wild Dog Rose, the resemblance to which is further borne out by the white eye. I believe it is one of the many cross-bred plants raised and sent out by Mr. Arends, and that its parents are *EITHERA speciosa* and its variety *rosea*, a beautiful plate of which is to be seen in the second volume of "Flora and Sylva." The newer form differs in having slightly larger flowers, more white in the eye, and a more delicate shade of pink on the rest of the petals, and thank goodness—or Mr. Arends—in possessing a much harder constitution, derived presumably from its white parent. The clump shown was planted on a newly-constructed bit of rock garden last April, and by July, in spite of many outlying portions going away in the baskets of my garden visitors, had formed the colony here seen, and continued to flower till late in October. E. A. BOWLES.

A JUNE BORDER OF IRISES AND LUPINES

COLOURED PLATE.

PLATE 1461.

A JUNE BORDER OF IRISES AND LUPINES.

IT is a great advantage in planning gardens, where suitable ground can be given, to allot a certain number of enclosed spaces for the flowers of a limited season only. It enables the designer to create a complete picture of flower beauty in a way that cannot be done

where the bloom has to be spread over a longer time. Colour photography from Nature has not yet reached such a degree of precision and accuracy as can do justice to a careful scheme of colour grouping, but the illustration may serve as a suggestion of the effect of a double border, mainly of Flag Irises and Lupines, at their fullest bloom in June.

The Lupines are of three kinds: the perennial, in five distinct colourings — white, purple-blue, pale purple shading to white, pink and red-purple; then Tree Lupines, white and yellow; and the good hybrid, Somerset, which, I believe, we owe to Messrs. Kelway of Langport. It is not so coarse in growth as the ordinary Tree Lupine, is very full of flower, and can have its lifetime prolonged for several years by severe pruning after blooming, some whole branches being cut away and the remainder shortened back. The pale purple-shaded perennial Lupine is a very fine plant, differing in character from the usual kinds that are so easily grown from seed, in that its whole growth is larger and handsomer, but perfectly balanced and proportioned, with a form of rare perfection, both of leaf and flower-spike. Increase of size, in plants of the same nature, often gives an impression of coarseness; but in the case of this good Lupine the plant is more refined, although larger than its fellows. With me it never bears seed—all the others seed freely.

The white Tree Lupine is a charming plant both for such a border and for groups or single plants at shrubby edges. As I know it, it is shorter-lived than Somerset, and is at its best the second year from seed. There are pink China Roses in the June borders that group charmingly with it. Among the purple Irises, a very useful plant is *Peltaria alliacea*, not so well known as its merit deserves. It is the white mass in the picture just this side of the tall yellow Lupine; another mass of the same is further away on the right-hand side. It is a cruciferous plant, bearing spreading corymbs of soft white bloom; the individual flowers are of the Sweet Alyssum class, but of a warmer white and more showy. Nothing could better set off the masses of purple Iris or

the pink of the China Rose. When the bloom is over, the lower parts of the stem have a half-woody, Cabbage-stalk appearance that makes one think that the plant is done, but after the stems are cut down it spreads out at the root

The borders are arranged in colour groups, masses of purple and white, with the pink of China Rose and pink Lupine passing to pale and strong yellows, and then again through pale yellows to purple, white and pink. Irises of red-purple colouring have a group to themselves, with red-purple Lupine and a groundwork of the red-bronze

FLOWERING SPRAY OF GARRYA ELLIPTICA, ONE OF THE MOST BEAUTIFUL HARDY SHRUBS IN THE WINTER GARDEN.

foliage of *Heuchera Richardsonii*; but they also pass through those that incline to pink, to the pure pink of the China Roses, and then to white. *Olearia Gunnii* is used for white bloom, and small bushes of Golden Privet among the yellows. A taller bush of Golden Privet looks over the Yew hedge, and from some aspects joins in with the yellow. The pretty Catmint (*Nepeta Mussinii*) and white and pink Pinks come close to the path edges.

THE FLOWER GARDEN.

THE FLOWER GARDEN IN WINTER.

HOW deep-rooted are many of the fallacies connected with the garden! Many an one, whose garden during the months of summer and autumn was resplendent with floral glories, as the fallen leaves make a thick carpet over "fair child"

over to desolation, accepting in its entirety the false dictum, "nothing will grow in winter," and consequently his garden is as dreary and depressing as the days themselves. No garden, however small, need be destitute of flowers all the winter months. With the first severe frost the summer delights must wither and die; but many plants defy the weather of a normal winter and repay the care bestowed upon them by giving us that most prized luxury—a flower in winter.

First, I would mention *Jasminum nudiflorum*, which will grow in almost any situation and in almost any soil. Allowed to climb at will over an arbour or paling fence, or closely tied back on to a wall, its beautiful yellow blossoms, springing direct from the leafless stems, opening in late November and onwards, form a patch of colour which must be seen to be fully appreciated. The sprays of blossoms last well in water, thus affording an extra pleasure for the home.

Next, the brilliant berries of *Crataegus Pyracantha*, with its background of dull green leaves trained upon the wall of a house, afford a mass of dazzling brightness upon the darkest of days. This evergreen plant requires little attention when once established, except the pruning away of excessive growths, and, together with *Jasminum nudiflorum*, should find a place in every garden.

Another plant that will thrive in almost every position and afford colour when the Jasmine has finished flowering is *Cydonia japonica*. Given a south aspect, in favourable soil it will reward the grower with an abundance of crimson blossoms, which can also be utilised for indoor decoration. The plant should not be too severely pruned, and in the summer months a mulching of manure will be beneficial.

Coming to the garden beds proper, *Helleborus niger* (Christmas Rose) will provide the necessary white blossoms. Christmas Roses, however, are all the better if protected from wet by either a hand-light or a bell-glass, so arranged that plenty of air circulates round the plants. Thus grown, they will last several years and be an ever-welcome treasure in midwinter. The Violet, given slight protection and well grown on a

G. J.

sunny border, can be coaxed into bloom before Christmas, and will supply the table for many weeks. The writer made it his proud boast that for years his Christmas gift to his mother was a bunch of her much-loved Violets, picked from a warm border on the south side of the house and grown as before stated. The Primrose, too, is most amenable to the same treatment, *Primula vulgaris alba flore pleno* being especially so, producing an abundance of double white blossoms, which are the better if protected as suggested for Christmas Roses.

For the shady parts of the garden—along walks and, in fact, in any position except a very dry and hot one—the Winter Aconite (*Eranthis hyemalis*) will flourish, imparting beauty and brightness to the garden in January and February. The Winter Aconite, so called from its time of flowering, is a sparkling gem, a golden cup set in emerald green, for the bloom springs direct from the centre of the leaf. Winter Aconites are very hardy, and are often to be seen pushing upwards through the snow.

One often marvels why such a hardy and beautiful winter or early spring flower as the *Chionodoxa*, the *Glory of the Snow*, is so seldom seen in small gardens. The cheapness of the bulbs places it within the reach of all, and, grown in combination with Snowdrops, the garden would be enriched for many years to come, as the bulbs, once planted, may remain untouched. The advent of that "herald of the sun," the *Crocus*, with its glorious golden cups upreared beyond its graceful foliage, is accompanied by the brilliance of *Arabis*, *Aubrietia*, *Hepatica*, *Myosotis* and *Primroses*, and once more the songs of birds are heard in the trees and the earth awakens to renewed life. S. W.

[There are other flowers that brave the elements in winter, such, for instance, as the *Winter Sweet* (*Chimonanthus fragrans*), *Wych Hazels* or *Hamamelis*, and *Garrya elliptica*, a winter spray of which we give an illustration on page 638. Doubtless there are others that may be called to mind, and we invite short notes from readers about them.—ED.]

AN INTERESTING WINTER IRIS.

ONE of the most interesting plants at the meeting of the Royal Horticultural Society, held on the 3rd inst., was the charming little *Iris* of which we give an illustration. This was shown by Messrs. R. Wallace and Co., and is an albino form of *Iris Vartanii*, its full name being *I. Vartanii White Pearl*. *I. Vartanii* belongs to the *reticulata* group, which comprises some of the daintiest and sweetest-scented of our winter flowers, and was sent to the late Sir Michael Foster by Dr. Vartan of Nazareth, after whom it was named. The variety *White Pearl* was sent to this country from Palestine in 1910 as a white form of *I. histrioides*. The flowers are pure white with the exception of a yellow bar on the falls.

THE ROSE GARDEN.

NOTES ON THE NEWER ROSES.

(Continued from page 625.)

SOME DECORATIVE VARIETIES.

I HAVE thought it advisable to qualify the heading of these notes. One can keep more or less closely in touch with new exhibition varieties, although that is getting increasingly difficult, but when one comes to ones that are not exhibition varieties, but embrace all the other sections, it is frankly impossible, and even the largest of our trade

of all the decorative or garden Roses is that known as the perpetual-flowering climbers; they are still very few and far between, and it is here that one may reasonably expect the greatest advance to be made in the near future. At the moment they do not number more than a dozen good varieties, and if one excludes the climbing sports, it would be difficult to name a really satisfactory dozen. To compare this with the selection that all the other sections afford shows at once the need and the truth of my statement. We look, then, to our raisers of new Roses with some hope that they will devote their attention to this class; the demand is here and pressing, only the supply is wanting. Very few of the non-climbers are perpetual flowering, the majority giving us an abundance of flowers, it is true, but spread over, say, six weeks instead of six months. In dealing with the climbers I shall not divide them into classes, but will take them alphabetically, indicating, as I come to them, the class to which the individual Rose belongs.

Ariel (Paul and Son, 1910), Climbing Polyantha.—This is a single-flowered Rose of excellent habit and much beauty. It has been described as a single-flowered "Tea Rambler." It has large flowers of a bright pink, with coppery buds, and a pretty bronze foliage that helps the general decorative effect. It has been given the Royal Horticultural Society's award of merit, and is a welcome addition to the singles. It retains its petals for a considerable time and is very free flowering.

Aviateur Bleriot (Fauque et Fils, 1910), *wichuraiana*.—A very pretty small or medium sized saffron yellow. Excellent foliage and habit. It has grown well with me this last season, and promises to be an acquisition to the yellow-flowering *wichuraianas*. It retains the colour of its flowers for a considerably longer period than the majority of the yellows.

Climbing Lady Ashtown (Bradley, 1910), Climbing Hybrid Tea.—This, if freely syringed to prevent mildew, promises to be an acquisition. My plant has grown all right and has given me some excellent flowers, especially early in the season. The type is now too well known to need description.

Climbing Richmond (Alex. Dickson and Sons, Limited, 1912), Climbing Hybrid Tea.—This, if fixed, should be particularly useful, both inside and out. As seen growing at Newtownards it was quite satisfactory.

Climbing Souv. de Pierre Notting (F. Cant and Co., 1912), Climbing Tea.—My plant of this has made growths 12 feet long this season. The blooms, one is inclined

to think, have less of the damaged or short outside petal; that is the only fault of the type. I suppose there is hardly a Rose that per plant gives us more flowers than *Souv. de Pierre Notting*, and if this sport will flower as freely—and I believe it will—then we have at once the best yellow climbing Rose.

HERBERT E. MOLYNEUX.

(To be continued.)

IRIS VARTANII WHITE PEARL, A RARE AND BEAUTIFUL WINTER-FLOWERING VARIETY. (Two-thirds natural size.)

growers have given up the task. I only propose in these notes to touch on those varieties that I have grown, or that have been specially recommended to me by reliable judges who have tested them. I shall deal, first of all, with the climbers or semi-climbers, then the dwarfs in their respective classes or sections. I think it will be generally admitted that the section which is the weakest

GARDENING FOR BEGINNERS.

HOTBEDS AND FRAMES FOR WINTER USE.

IN the depth of winter, when many buds are hard and dormant, the forcing of certain plants into new growth by means of heat from hotbeds is very interesting and absorbing work. Then there is the use of cold frames for the preservation of many kinds of plants which are required for the flower garden the following summer, and which would not withstand the winter weather if left entirely unprotected. Those cultivators who possess frames are enabled to grow many kinds of plants that it would be almost impossible to have without them. Then, the work of raising seedlings can be engaged in much earlier in the year than would be the case if the seeds had to be sown direct in unprotected borders.

The Material for Hotbeds.—This may consist of stable litter entirely, litter and tree leaves mixed, or leaves alone. The most satisfactory hotbeds are those constructed of stable litter and leaves, in the proportion of three parts of the former to one of the latter. Littery manure, taken direct from a heap which has heated and burned, will not answer our purpose, because the material will not engender heat a second time. The material must be collected fresh every day, and spread out in an open shed so that it cannot heat violently; moreover, it must be turned over every day. When sufficient has been collected, make up the bed quickly; do not half build it and then allow it to remain for several days, exposed, perhaps, to heavy rains. The bed must be considerably wider each way than the frame which is to be placed on it, because there is never much heat near the outer edges of the bed, and, furthermore, a rather wide bed forms a more secure base for the frame and its contents.

Fig. A.—No. 1 shows the frame on the bed (No. 2), which is wider than the frame by 18 inches on each side. The bed (No. 3) must be built up by well shaking

THE HOTBED MUST BE MADE LARGER THAN THE FRAME, AS SHOWN AT NOS. 2 AND 3.

out the litter and leaves, and thoroughly mixing them loosely as each layer is placed in position. As the material will settle down considerably, the bed should be quite 4 feet 6 inches high when the frame is placed on it. The centre of the bed (No. 4) must be higher than the other parts, as it will sink the most. Nos. 5, 5 show the margin of the hotbed beyond the frame. Such a bed is most useful on which to raise seedlings, for propagating cuttings, for the plunging of the pots when plants

have been recently repotted, and for raising early vegetables and salad plants. A cool, wooden frame lasts longer if placed on rows of bricks, as shown at No. 6. It is a mistake to draw up the glass light from the bottom so as to allow rain-water to drip in, as shown at No. 7. When ventilation is necessary, the light should be tilted at the top, as shown at No. 8.

Fig. B.—Many persons are unable to procure manure to build hotbeds, but nearly all possessors of gardens have walls or close fences facing south, and against such structures cheap frames may be placed, as shown at No. 1. The fence is shown at No. 2, and the frame, or frames, may be continued as shown at No. 3. It is really not necessary to have divisions in such frames if used for the raising of half-hardy annuals, vegetable or salad seedlings; but, if required, wooden divisions can easily be put in. A strong board, fastened to posts driven into the ground, will form the front of the frame, and two boards, on edge, the end. A 4-inch by 2½-inch rafter piece, screwed to the fence, will do to fasten the hinges of the frames to, the latter being lifted up in front. No. 4 shows a permanent wall 9 inches thick, and No. 5 a brick wall 4½ inches thick. A frame facing north is readily made, in the bed of which, as shown at No. 6, many kinds of young plants and seedlings which require cool treatment may be safely kept. The span-roofed frame is extremely useful, and should be placed in an open quarter on a bed of ashes, if possible. Where all the plants are small, a low stage may be fixed in the centre, as shown at No. 7, for the accommodation of pot plants; while others, and boxes containing cuttings and seedlings, should be placed at the sides, as shown at Nos. 8, 8. Both lights (Nos. 9, 9) may be raised at the same time, or one at a time, according to the direction of the wind.

G. G.

COLD FRAMES PLACED AGAINST WALLS OR FENCES ARE VERY USEFUL DURING THE WINTER AND EARLY SPRING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Bedding Geraniums.—Some little care is necessary at this season, or the plants will quickly damp, and what may appear to be a healthy-rooted cutting will rot away at the level of the soil. Give a circulation of air whenever possible, and look the plants over carefully, removing any decayed foliage. Water will need to be very sparingly applied.

Border Carnations.—It is more than likely that with the wet state of the ground, if we get a spell of severe frosts the plants will be lifted. In that case make them firm at the base, and, whenever the state of the ground permits, loosen the soil between them and give a sprinkling of soot around them. If the cinder-ashes that were placed around the plants have been washed down, renew them, as they make the plants immune from attacks by slugs.

The Rock Garden.

Daphnes.—Few flowering shrubs are more highly appreciated on the rockery than one or two of the species of these fragrant shrubs, and their establishment is not always easily effected, thus making them the more valuable. *Daphne Mezereum* and its white variety are not difficult subjects for the bolder portion, but *D. blagayana* is a treasure worth any amount of trouble to establish. *D. Cneorum* and variety *majus* are both beautiful for flowering in April and May. In sheltered sites they may be planted out of pots now during open weather, but, if well established in pots, it will be preferable to allow them to remain and carefully transplant in early spring. They like a fairly damp position, but not waterlogged, as a sour soil is fatal. Peat or decayed leaf-mould and road sand should be incorporated freely, and an open position chosen for them.

The Shrubberies.

Variiegated Shrubs.—Providing, of course, that planting is discriminately carried out, many of our shrubberies and surroundings are considerably livened up by the use of deciduous and evergreen subjects bearing variegated foliage, and appended are a few that may be planted at this season with the confidence of their proving free-growing, valuable subjects. The golden and silver variegated forms of *Aralia chinensis*, *Cornus alba Spæthii* and *C. alba variegata*, *C. brachypoda variegata*, *C. Mas elegantissima aurea* and *C. M. variegata*, *Diervilla florida versicolor* and *D. f. variegata*, *Forsythia viridissima variegata*, *Hibiscus syriacus variegatus*, *Kerria japonica variegata*, *Acer Negundo variegata*, *Philadelphus coronarius aureo variegatus*, *Rhamnus alaternus variegatus*, *Ribes nigrum variegatum*, *Aucubas* (in variety), *Elaeagnus pungens variegata*, *Euonymus radicans variegata* (for the border), *Hollies* (in variety), *Ligustrums*, *Osmanthus* and the variegated forms of *Vinca*.

The Hardy Fruit Garden.

Strawberries.—During suitable weather the beds out of doors may have a mulching of well-decayed manure applied to them.

Standard Apples.—These and other trees, such as Pears and Plums, that have become well established, and especially those that bore good crops last year, will benefit by having a dressing of good farmyard manure applied to the surface. I prefer to add this and cover over with just a sprinkling of the surface soil.

Peaches and Nectarines.—The pruning of these fruits is far better deferred till the early spring, as the young growths are sometimes apt to die back. The work may then, of course, be completed before the buds are on the move. The planting of trees may yet be done when the weather permits, though I prefer planting earlier while the ground is warm. Dwarf trees are usually preferred, with standards to occupy the top part of the wall while the dwarf-trained trees are establishing themselves, when the standards should be removed entirely.

Plants Under Glass.

Begonia Gloire de Lorraine.—Endeavour to keep these plants as attractive as possible by carefully attending to their requirements as regards watering.

Be careful to avoid excess and give a little stimulant, avoiding the use of strong manures, which cause the flowers to pass quickly. Keep the flowers picked off and any tying-up seen to. These plants are wonderfully pretty if suspended from the roof of a warm house in baskets. The female flowers are interesting to watch for, and are usually terminal.

Amaryllis.—A small portion of the bulbs may be top-dressed or potted and started for flowering in another six weeks or so. These will do much better if the pots can be plunged in a little bottom-heat and kept damped over.

Chrysanthemums.—Cuttings of the plants that require a long season of growth for producing large blooms will very soon have to be inserted. Select those that come away from the rootstock for preference and choose sturdy stock. Little heat will be required; in fact, they may be rooted in a cold frame.

Fruits Under Glass.

The Starting of Houses.—As the houses and trees are got in readiness, until the time for starting into growth arrives they should be kept as freely ventilated as possible. Peach trees should, before they come into bloom, be fumigated so as to destroy any aphid that may be present, as this cannot be done while in flower without the possibility of injuring them.

Early Vines.—These require a little higher temperature than Peaches, and once or twice a day, as the weather allows, the rods should be damped over. By this I mean merely spraying, which will induce them to break more evenly, and for convenience and to encourage a more even break, the rods may be brought down and tied horizontally together, as the temperature is more even and it prevents a rush of sap to the extreme height, which occurs when they are tied up.

The Kitchen Garden.

Preparation of Ground.—While the ground is hard, continue to wheel manure on to the various plots ready for digging or trenching, and proceed with the work on heavy land as soon as possible, leaving the surface in a rough state so that the weather may act upon it. Where there is a natural deficiency of lime, strew some over the surface. Wood-ashes and other burnt garden refuse may be similarly employed, with the best effect.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Bad-Weather Occupations.—Iron stakes may be repainted, labels made and written on, Dahlia and Hollyhock stakes repointed and repainted, and wooden stakes that are much decayed at the points split and used again for lower-growing plants. Thick Bamboo canes split quite easily and are suitable for lighter-growing material. Assort them and tie them in bundles to be ready for summer.

Split Laths.—Plasterer's laths split in two or three and the edges trimmed and each pointed make durable stakes. They are not at all expensive, and a clever hand with his knife can manufacture a very large number in the course of a few bad-weather days. The ends may be charred, or at least be painted.

Seed Cleaning.—This is another necessary occupation which is best overtaken when outdoor labour is impossible. Bags with names ready written on should be prepared, and each variety cleaned and sealed before another is taken in hand. Carnation and Gladiolus seeds I keep in their seed-vessels till the time of sowing, but most others can be cleaned now and got ready for sowing.

The Vegetable Garden.

Ground Work.—If the greater portion of vacant ground has been cultivated, manure can be wheeled on during hard frosts and spread ready for digging in as opportunity and weather permit. I hesitate to cultivate ground while wet or covered with snow; but many who have still most of their garden undug and untrenched have no option but to proceed when they have time.

Composts.—All the accumulated rubbish of the past year should be turned, broken up and left in a neat heap for another year, and older material that has become decayed enough may be wheeled on to quarters yet to be trenched, to be buried well beneath the surface. It is of greater utility in heavy soils, where it may be lavishly used, than on those of a light nature.

Scotch Kale.—This vegetable is of great value in March and April. It is hardiest when planted on poor, hard soil, which may now, or soon, be enriched by means of a dressing of manure run along between the rows, to be forked in either now or later. Very often this vegetable is cut in a wasteful manner, the whole head being removed. A larger quantity of usable material is secured by cutting the leaves, one or two at a time, from a plant. These make an excellent substitute for Spinach, or may be cooked as a dish on their merits.

The Plant-Houses.

Hydrangeas.—Young plants should have been rested sufficiently to force for early blooming. They stand and appreciate a high, moist temperature, but till root-action recommences do not need much water at the root. Only the strongest plants with prominent buds should be selected for this purpose.

Hippeastrums.—If these are wanted early, a portion of the stock should be put into a house with a temperature of 55° to 60°. They will need no water at the root, but may be placed under the stages or anywhere till the points of the flower-scapes have pushed a little, when a higher temperature with moisture will cause the flower-stems to elongate rapidly.

Shrubs.—Such easy-to-force plants as Flowering Currants and *Rhododendron præcox* may be introduced to a structure with a medium temperature, in which they can be placed under stages or in any odd corner till the buds are at the breaking-point. Moisture is one of the essentials, and, if frequently syringed, water at the root will be seldom required.

Roses.—Those growing in borders should now be pruned. They are usually climbing varieties so cultivated, such as *Niphetos* and *Reine Marie Henriette*, and these must be distinguished, the last named requiring the few shoots that were allowed to mature to be reduced to strong wood capable of producing blooms. The first named, on the other hand, needs only to be carefully thinned. Tie the shoots out so that there is sufficient space for the young growths to fill without overcrowding. The addition of well-enriched compost, with a little dried blood added, will help them to break strongly.

Hardy Fruits.

Scale.—On Pear trees scale insects sometimes effect a lodgment, and it is difficult to exterminate those which hibernate out of the way close to walls. I have painted a badly-infested tree with sweet oil, omitting the buds when painting, with the best results. Trees only partially affected may be sprayed, and where Plum trees are attacked, spraying would be best for these too.

Apple Trees in Grass.—These should not be forgotten when dispensing the material from the compost and manure heaps. Sometimes I apply the manure, sometimes the compost, and both have a good effect in promoting a vigorous growth and increasing the bulk of fruit. Remains of wood fires are also valuable, but these are reserved for Apricots on a grass-covered border and for dessert Pears. All may be dressed with these materials at this time of year, spreading them nicely all over the surfaces so that every part may have an equal share and that the materials may be well weathered.

Raspberries.—If not done up for the year in autumn, these may now be taken in hand. Usually ours are finished, with the exception of cutting off the weakly points, which may be done now. If cow-manure can be had, it affords one of the best stimulants for this crop, but it should lie nine to twelve months before using. Some object to digging between the rows and stools of Raspberries. Personally I have no objection, but the spades are not used too near the plants, when deep digging results in root-pruning and the production of new roots into renewed soil annually.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

TWO OF THE FIRST ENGLISH FLOWER BOOKS. THEIR AUTHORS AND CONTENTS.

PARKINSON'S "Paradisus" is usually alluded to as the first work of any consequence in the English language in which the wants of the flower garden are placed first and foremost. This is undoubtedly correct if the intention of the author is the only consideration; but it is not wholly so if we look at the materialised expression of his mind in the book which he produced. It is impossible to entirely throw off the spirit of a long-accustomed environment all at once. Parkinson was no exception to this rule; so while we recognise the voice of the "Paradisus" to be that of the garden, the form is undoubtedly that of the herbal. Personally, I would describe this famous folio as the book of a transition period between the supremacy of the "physic" and the coming of the flower garden. The first half of the seventeenth century was the chrysalis stage, when the ability for healing was being discarded as the first and only desideratum of its occupants. Rea's "Flora seu de Florum Cultura" and Gilbert's "Florists' Vade Mecum" performed a valuable office at the first expanding of the new wings of beauty and pleasure which were henceforth to be distinctive marks of the English garden. It is this that gives them their great interest and historical value; for they mark the beginnings of a marvellous development, of which the end is still far out of sight.

Those who only know the exteriors of these two books may possibly think that I have coupled together two very unequal yoke fellows (one is a small folio and the other only a 12mo.). Size, however, is not always everything. It is not so here. There was work for both to do, and the numerous editions through which they passed clearly shows us that they did it, and that it was much appreciated. Moreover, in one sense they were not really two. The "Vade Mecum" was but the continuation of the older and larger "Flora," and breathed the self-same spirit, for its author had lived for some considerable time with John Rea, whose only daughter he had married, and through whom, after his father-in-law's death, he had inherited the garden in which his experience had been gained. The younger man alludes to the elder as the foremost florist of his time, whose collection of Tulips was unique, and who possessed among other rarities for which he was justly and widely known some of the finest July-flowers and Bears'-ears then in existence. His "long converse" with such an one gave him knowledge and skill; his good fortune in having such a garden as an object-lesson gave him practical experience; while his own early training and inclination enabled him to profit by all he had heard and seen:

If Jackanapes on Giant's shoulders be,
He hath no eyes, or else can farther see.

In this spirit he sends out two years after his father-in-law's death what he calls his "Pocket Companion to all Lovers of Flowers and their Propagation."

After this preamble I pass on to record what is known of the lives of these two old-world gardeners, and then, having done this, I hope I may take my readers with me when next week and the week following we turn over some of the pages of these two most interesting relics of the past—

the "Flora seu de Florum Cultura" of Rea and the "Florists' Vade Mecum" of Gilbert. But little is known of the former beyond what we can gather from his own writings. We have no knowledge of his birth or parentage. He seems to have lived the greater part of his life at Kinlet, near Bewdley in Worcestershire, a rural district, not naturally such an one as would be chosen for a garden, and which, in addition to its unkindliness, was very much out of the world. According to the notice in the "Dictionary of National Biography," he followed the calling of a nursery gardener; but I am disposed to doubt this because of certain expressions which he uses in his introductory letters, which, after the fashion of the time, are inserted in his book. In the preface to the reader in the first edition (1665) he says: "Forty years are now completed since first I began to be a Planter and to dedicate more time than I could well have spared for Diversion to that lovely Recreation"; and, again, that he finds himself in old age more happy in this "retired solitude than in all the bustles and busie employments of my passed days." To Sir Thomas Hanmer he writes that but for his encouragement and help he would have been "less knowing in this delight," and that he would "long since have grown out of love with his garden." He certainly planned the gardens at Gerard's Bromley for Charles, the fourth Baron Gerard, but I would suggest that he did this more as a friend than as a professional. It was to this man that he dedicates the first edition of his "Flora," and to the successor in the title, Digby, the second in 1676. Rea died in November, 1681, leaving his holding to his daughter Minerva, who was then the wife of Samuel Gilbert, and his collection of Tulips to one Thomas Tassell of Wyche. As far as is known, he was a one-book man, for his "Flora" in which he recorded his life experience as a "Planter" and florist is the only work of his of which there is any record. JOSEPH JACOB.

(To be continued.)

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

CARNATIONS FAILING (*Wimborne*).—The example sent had been bored by a wireworm, the central part of the stem having been cleared out entirely. Had it not failed from that cause, it would probably have done so owing to the poor attempt at layering evidenced by the example sent. Contrary to custom, the nib had been formed on the upper surface of the layer instead of underneath, while its feather-edged tip or point would almost preclude the possibility of its rooting. Moreover, the cut was little more than a quarter of an inch long instead of fully 1 inch, beginning immediately at the base of one joint and extending to the next. Such imperfect work may be responsible for more failures than the pest to which we have referred.

CARNATIONS AND SOIL (*E. G. F.*).—The plant you submit has been attacked by stem ceworm, which, in the existing state of things, is likely to be transmitted to the young stock. Nothing short of a complete change of stock and soil is calculated to be of much service.

HERBACEOUS BORDER (*Lynley*).—There are many plants which do quite well over chalk, the presence of which is not so important as the depth of soil available. If you will give us an idea as to the depth of soil and the size of the border you have in mind, we shall be in a position to help you. It is the width of the border that is material, as obviously the stately plants suited to a 12-foot-wide border would be out of place in one of 4 feet or 5 feet in width.

DARK PURPLE CARPETING PLANT (*P. C.*).—*Viola cornuta atropurpurea* is the plant you require. It is good in colour, an excellent carpeter of the soil, albeit a little loose towards the end of the year, and a great bloomer. You could plant it now, a few weeks hence, or in spring, say, March, if a late summer display is most desired. Even when not in flower, the fresh green of its foliage is a great gain. Happily, too, the plant is a good perennial and may go on for two or three seasons in your district with annual cutting and mulching. You should write to Messrs. Gunn, Olton, near Birmingham, who specialise in the plant.

WALLFLOWERS LOOSE IN BEDS (*J. L. S.*).—The Wallflower is a sparse-rooting subject, and this, in conjunction with your heavy and wet soil, is largely responsible for the trouble. It is highly probable, too, that owing to the wetness of the soil the original planting was insufficiently firmly done, or the plants insufficiently deeply planted to get a firm hold of the soil. What usually happens in the case of wet soils is that the plant is swayed by wind and storm, and a socket-like, watertight hole resulting, the plant not infrequently perishes from frost, which gets into direct touch with the plant. In all the circumstances we incline to the opinion that the planting is chiefly at fault. We say this advisedly, inasmuch as for years we have had to contend with one of the worst types of clay soil, and the planting, too, of large numbers of these same plants. If the soil was abnormally wet, the planting was done from a plank, having first strewed the surface of the bed with light material, Cocoanut fibre or old potting material. The method of planting was that of the small hand-fork for each plant, applying finger and thumb pressure to each, the lighter material being worked close to the plants meanwhile. You should do likewise. To keep the surface soil "loose and open" does not imply that the plant should be at liberty to indulge in calisthenic exercises. All plants should have the soil so pressed about their stems that they are held firmly in position, and water and air in contact directly excluded thereby.

TREES AND SHRUBS.

HEDGE OF VERONICA (*W. H.*).—The best time to cut your Veronica hedge back would be April. If cut back now it would look very ugly all the winter and some of the branches would probably die, whereas if the work is deferred until April new shoots will appear almost at once and cover up the old cuts. In the event of the weather being very dry when the work is done, you would do well to syringe the plants twice a day until the new shoots put in an appearance.

TO REDUCE THE SIZE OF AN OLD HOLLY HEDGE (*H. E. C.*).—It is not advisable to cut your Holly hedge back severely at the present time, but you may safely cut it back by half next April. If cut back now no new wood can be made for at least six months, but if the work is done in April new shoots will appear almost at once. The sides should be cut in as well as the top, and if the centre of the hedge is choked with leaves or dead wood, such should be removed. A good hosing would have beneficial results, for it would wash away any accumulation of dust or dirt from the bark. It would not be advisable to cut out the old stumps, for that would tend to weaken the hedge and cause gaps. You will need to be careful for several years with the pruning, for if the top shoots are not kept severely checked they will rob the side shoots and the hedge will not thicken well. Should the weather be dry when the work is done, a good syringing twice a day for a few weeks would help in the production of new shoots. A surface-dressing of well-rotted manure would also do good. If there are any very thin places in the hedge you may be able to insert a young plant or two here and there. April is an excellent time for planting Hollies.

FRUIT GARDEN.

MUSCAT GRAPES GONE WRONG (*G. C. H.*).—A too cold, damp atmosphere at night when the Grapes are dead ripe will bring about shanking, especially if the Vines had received a heavy watering a day or a few days before. It is evident that the Vines had a chill or set-back from some cause, and therefore the best thing you can do is to endeavour to bring the Vines back to good health again. To this end we would lift the roots in the inside border to within 18 inches of the front wall. To do this you would have to open a trench at the bottom of the border furthest from the wall. (The depth of the trench will depend on how deep the roots are; you must get to the bottom of them.) Remove all the old soil, and be careful to preserve intact all the roots you come across. Replant carefully, after cutting back the cankered and lifeless roots, in fresh, best Vine soil. The outside border should be served in the same way next year. By doing this you will obtain a nice healthy body of roots, which will carry your old Vines successfully through many years of good cropping again.

THE GREENHOUSE.

PELARGONIUMS (*Amateur*).—In order to obtain the best results from Pelargoniums in the winter, they should be firmly potted in some good soil, mainly consisting of loam, lightened by a little leaf-mould and sand. When the plants in the pots are well furnished with roots, an occasional stimulant may be given, but care must be taken that it is not too strong. Stood in a sunny spot and not overcrowded, the plants will make good, short-jointed wood, such as will flower well in the winter. The flower-buds should be picked off when the plants are taken into the greenhouse, where a light, buoyant atmosphere should be maintained.

NERIUM OLEANDER (*H. R.*).—In this country the Oleander needs the protection of a greenhouse, or, at all events, to be so situated that it is quite safe from frost. The Oleander is naturally of a loose, Willow-like habit of growth, and if the leading shoots are frequently pinched in order to ensure a neat bush, it will not flower in a satisfactory manner. It needs to be potted in ordinary compost, such as a mixture of loam, leaf-mould and sand; and the rooted sucker which you removed from the parent plant would have been all the better if leaf-mould or peat instead of manure had formed one of the ingredients of the potting compost. As your plant is in a sorry plight, we should advise you to wait until the end of February or the early part of March, and then report it, taking away as much of the old soil as can be done without injury to the roots.

THE COST OF BUILDING A GREENHOUSE (*Old Gardener*).—The cost of the structure, not including the brickwork, would be about fifteen shillings per foot run of house. If there are no side-lights, the cost would be about ten shillings per foot run. You do not state how high the brick walls would be. You can easily ascertain the cost of the walls locally. The woodwork should be of best red deal, well seasoned; 21oz. glass for the roof, 16oz. for the sides, bottom putty, no top putty, the squares of glass being held in position by sprigs. The wood must be primed, and have one coat of paint before glazing and two coats after glazing. The cost of boiler, flow and return 4-inch hot-water pipes, expansion box, air pipes, rubber joint fittings, stack pipe and stoking tools would be about eight pounds ten shillings.

ROSE GARDEN.

SAMPLE OF SOIL (*Appreciative*).—The soil sent is fairly good for Roses, but it would be much improved if you could add some pulverised clay, to give it more body, and it will need to be well enriched with good, well-decayed manure. Add some basic slag to the subsoil when trenching, and as you plant your Roses give each plant a handful of bone meal.

ROSE SPORT (*Rosarian*).—The possibility of your having to leave England is a very great drawback to success with your plant. In such a long journey as that to Australia in the spring, you would most certainly lose the tip of the shoot; but we should say the Rose would give the sport, even though the tip of the shoot died back. Generally, the sport will come true from any eye springing from the same growth. The best plan, now that you have missed budding it, would be to get your local nurseryman to graft a plant for you. Then dig the plant up at once and put it into a small pot. If you go to Australia you could pack the tree in the pot in a box, and you might be successful with it. A few Briars culled from the hedges now would enable you to bud the sport next summer, providing you do not leave England.

DOROTHY PERKINS AS A POT ROSE (*R. W. D.*).—You should have put the plants into a greenhouse and kept them growing after you had cut them back. The best way to handle such Roses is to reduce the old growths to about one or two, and then place the plants in a structure where a nice growing atmosphere can be maintained, and a temperature of about fifty-five degrees by night. Plenty of atmospheric moisture, and also moisture to the roots, will soon induce new growths, which by August would be some 15 feet to 20 feet long. The plants are by that time ready to place outdoors. Tie the growths to tall canes in an upright position, and stand the plants upon ashes in a sunny spot, preferably against a greenhouse. They will ripen off well, and in November may be placed in a cold house. When you wish to start them, twine the growths around canes in a pyramidal or columnar form, or any shape you like, and give them gentle heat at first and plenty of air. About fourteen weeks should be allowed from the starting to the blooming; but as soon as the buds show colour, remove the plants to a cool house, where development will be slower, but the colour much improved. During the growing period abundance of water is needed, also frequent syringings to keep down red spider.

MISCELLANEOUS.

CELERY LEAF BLIGHT (*J. S.*).—You are quite right in taking the fungus on Celery to be different from Cercospora. In our experience—and we have examined hundreds of diseased Celery plants—Cercospora is now rarely found, the common cause being Septoria petroselinii var. Apil, the fungus you describe so well. You will find some descriptions of Septorias in "Cooke's Microscopic Fungi." The Perithecia are not like those of the Erysiphe, and the fungus itself grows *inside* the leaf, not *outside*. It is difficult to find a book giving recognisable descriptions of all the fungi likely to be met with, but perhaps Massee's "Diseases of Cultivated Plants" would meet your need.

Saccard's, which contains descriptions of all known fungi, is in twenty large volumes, and costs about eighty pounds.

NAMES OF PLANTS.—*J. B.*—*Tecoma radicans* (the Trumpet Flower).

NAMES OF FRUIT.—*A. V. H.*—Apples: 1, Lady Henniker; 2, Wellington; 3, Norfolk Beautin. Pears: 1, Winter Nellis; 2, Brown Beauté; 3, Baronne de Melé.

BOOKS.

Tulips.*—As an editorial footnote to the preface tells us, this is the first book entirely devoted to Tulips published in English. I hope it is but a forerunner, and that before we are much older the long-needed monograph of the genus will issue from the busy brain of our own countryman who, having completed his work on the Iris genus, is now turning his attention to Tulipa. But a monograph on botanical lines only will still leave a void, for as a garden flower the Tulip possesses a history and literature as sensational and interesting as any plant. The compression necessary to keep this new volume of the "Present-Day Gardening Series" uniform with its brethren has, to my mind, stamped it with the nature of a *hors d'œuvre*, to whet our appetites for the banquet we expect from the hand of the author, whose love of the Tulip for its own beauty and his knowledge of its past history, combined with the possession of a singularly rich collection of books and papers relating to it, all point so clearly to his being the right man to prepare the feast. So far as the book goes it is excellent, and if the writing of it has stimulated his desire to go further, we may forgive its brevity.

The late-flowering Tulips are gaining rapidly in favour. The gardening public is at last beginning to realise their beauty and true economy. Much less frequently than formerly, when I speak of my May heyday of Tulips, do I hear it said: "Tulips now? Why, ours have been over a long time."

Growing Tulips still means for a few poor benighted souls the forcing of prim little Duc Van Thols. How I do dislike their mean proportions and crude colours, their anæmic leaves and precocious appearances on Christmas dinner-tables, caricatures as they are of the real thing. Other few are still content with a few pots or bedded-out designs of early Tulips, both double and single, dumpy and stiff though many of them be. It is such an extravagant form of gardening, too, for very seldom do any of them find an English garden a sufficiently congenial home to induce them to settle down and produce a good flowering bulb for the next season, and Dutch-grown bulbs must be bought to renew them. The advent of the Darwins and the revival of the Cottage Tulips have taught us that instead of purchasing fresh stocks each season, anyone with patience for reasonable care, and a soil richer than cinders and less solid than blue lias, can confidently look for an annual increase of their bulbs. Not only in Europe, but in America and New Zealand there is a yearly increasing demand for May-flowering Tulips. This has produced the sudden rise in prices mentioned in the introductory chapter; but to counter-balance this evil for the planter, the author confesses that it has induced him to devote a larger space to their consideration, and prophesies that they will prove to be the twentieth century Tulips.

The book is well thought out and planned. Its twenty-two chapters vary much in length, but each one is devoted to a single aspect of the Tulip. This tends to clearness and makes the book valuable for quick reference. Chapter II., on "Chronology

* "Tulips," by the Rev. Joseph Jacob; price 1s. 6d. net.

and Bibliography," is a model of the compression of important information into a small compass.

In a few instances one would like to have the references to the authorities given, e.g., the first notices of double and of Parrot Tulips.

Chapter III. is a delightfully clear account of the Tulip mania of the seventeenth century; the fourth, a vocabulary of the technical terms that have grown up among the cultivators of the flower.

Then nine chapters deal with various divisions of Tulips, such as Early, Double, Species, Florist, &c. The useful chapters on cultivation under glass and in the open; on colour planning, propagation and diseases, are full of practical hints and warnings—the fruits of years of personal experience—and would alone justify the publication of the book. In addition to the carefully compiled lists of the best sorts, given in the chapters devoted to the divisions, there is one on the selection of varieties for various uses that seems very useful, especially for the beginner, to whom it should be a saving of expense and disappointment if carefully studied and followed.

As it is customary in a notice of this kind to hunt out and pillory misprints or mistakes, I have searched carefully, but find little to report. I hope to see a second edition, and in it a further simplification in the vocabulary of the definition of bizarre and byblœmen. At present, to the uninitiated it reads as though *T. mauriana* or any self yellow Tulip might be a bizarre, in that they possess yellow bases. Under the heading "Roses" the mention of the markings being upon a white ground makes the matter clear for all.

Under "Italian," on page 20, I should like to see "A generic name for that group of species," &c., altered to "A name for that group of species found," &c. On page 27 Proserpine is mentioned twice, first among the red and cerise forms, and again among the various. Good though it be, this is unfair and, I feel sure, unintentional favouritism. Page 48: Zwanenberg Nurseries have acquired a new name in the compositor's hands, I fancy. Page 49: Cramoisi Brilliant has changed an "i" for an "e." *T. elegans* is in its right place on page 36, among the Cottage varieties, and, I believe, appears wrongly among the species (even qualified, as it is, as a doubtful one) on page 52, for I have been told by a great Dutch authority that *elegans*, *e. alba*, *retroflexa* and *fulgens* all appeared in the same seed-bed and were of garden origin. I am sorry to find no praise of *fulgens* in the book; the tallest of all and of so fine a crimson, I rank it as one of the very best for massing in borders. It has a very fine effect among Iris foliage, between groups of late-flowering ones such as *I. ochroleuca* and *Monnieri*, it is very useful to give colour before they are out.

In lines 11 and 12 on page 63 the little word "an" has played general post and needs another move; and winter has usurped the place of summer on page 78 as relentlessly as it often does in an English June.

The coloured plates are marvels of beauty to find in a book of such low price. Especially excellent are No. VIII., of *Euterpe* and *Frans Hals*, and No. III., of *Suzon* and *Farncombe Sanders*. But I must grumble at the arrangement of No. VII., in which Sir Harry utterly dwarfs the really taller *Solfatare*. The colouring is delightful in all except No. V., where the orange shades of *Prince of Austria* and *Fred Moore* are not done full justice; but, after all, it may be they suffer from being of so difficult a colour to reproduce and from the charming delicacy of effect in the other plates. E. A. BOWLES.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

General Index to this Volume.—With this issue, which completes Vol. LXXVI., we are presenting a general index, together with a title-page, suitable for binding with the whole of the numbers published during 1912. Following our usual custom, we shall next week present, in addition to the coloured plate, an almanack, giving the dates of all the principal horticultural shows in the country. That number will be specially enlarged, and contain numerous articles by the best authorities on the subject.

Protecting Roses from Frost.—During the next few weeks we may expect very severe frosts, and we would remind readers that the more tender of the Tea Roses, as well as newly-planted Hybrid Teas, should have some protection. Where the soil is friable enough, this may be heaped, conical fashion, well up the stems. On very heavy soil, coal-ashes, or even fine porous soil prepared for the purpose, may be employed. We have found either of these preferable to straw or manure.

A Good Christmas Rose.—*Helleborus niger* major, the equivalent of the Bath variety, is, perhaps, the most reliable of the Christmas Roses generally in point of time; it is usually with us at this season. This year the equally good *Mme. Fourcade* is with us, too, and if a little less pure than the first, it is bolder and showier as a garden plant. The twain, however, are so precious that there is room for both, and in some quantity, too. A few flowers with shrubs in a bowl make a rather pretty informal display, and the flowers endure so well and so long.

The Rev. W. Wilks.—It is interesting to note that when the annual general meeting of the Royal Horticultural Society is held in February next, the Rev. W. Wilks will have acted as secretary to the society for twenty-five years. At the time of his appointment the society had just left South Kensington and was in very low water, but, owing in no small measure to the efforts of Mr. Wilks, it has since then forged ahead and is now in a most flourishing condition. We would suggest that the annual general meeting, to which we have referred, would be a fitting occasion to make some recognition of the invaluable services he has rendered the society, and we would like to know that the Council had some scheme in hand with this object in view.

Lilies in Flower.—Not so very many years ago it would have been looked upon as little short of a miracle to see Lilies of different kinds in flower at Christmas, but now they may be had in great numbers at this season. The silvery trumpets of *Lilium longiflorum* are everywhere in evidence, and besides these there are the white and coloured

forms of *L. speciosum*, the golden-rayed *L. auratum*, and, occasionally, a few flowers of the Japanese form of *L. tigrinum*. All this is brought about by the retarding of the bulbs in cold chambers, a practice that has now been in vogue for about ten years. After being retarded beyond their usual season of blooming, the bulbs need only to be placed under conditions favourable to growth, when they will start away at once.

Begonia Glory of Cincinnati.—This is a very fine form of the *Gloire de Lorraine* section, forming as it does a bolder plant, with larger flowers than those of the type. Besides this, the leaves have more of the peltate character common to the typical *Begonia socotrana* than has *Gloire de Lorraine* itself. The flowers hold themselves in a prominent position, so that, viewed in a mass, there is a far greater display of blossoms than from a corresponding number of the ordinary *Gloire de Lorraine*. As indicated by its name, this *Begonia* was raised in the United States of America. It was last winter given an award of merit by the Royal Horticultural Society. It is a good winter variety for the greenhouse.

Plants Flowering Out of Season.—Last week we drew attention to the fact that Lenten Roses and a number of other plants were flowering freely. Since then we have seen in the London district flowers of the *Woodruff*, *Adonis anurensis*, *Crocus Imperati*, *Hamamelis arborea*, *Viola gracilis*, *Pyrus japonica*, *Double Arabis*, *Potentilla rupestris*, *Aubrietias*, *Phlox setacea*, *Polygala Chamæbuxus*, *Daphne Mezereum*, *Saxifraga Fernandii-Coburgii*, *Ionopodium acaule*, *Veronica prostrata*, *Centaurea montana*, *Viola Bullion* and *Anemone blanda*. The last named, though not tully open, is sufficiently forward to enable the colour of the buds to be seen. On the next page we print a letter from Mr. F. H. Chapman, in which he gives a list of plants flowering just now in his garden at Rye, Sussex.

New Sources of Paper.—The current issue of the *Kew Bulletin* contains some particularly interesting details of new sources of paper. The most important of these is the tropical plant known as *Hedychium coronarium*, examples of which can be seen in House No. 15 at Kew. Messrs. Clayton, Beadie and Stevens of London have experimented largely with this plant, and find that it yields paper of greater tensile strength than the strongest Manila papers produced. Its elasticity and folding qualities are said to be exceptional, and it can be made to bear ink and possess parchment qualities without sizing or other special treatment. *Amomum hemisphericum*, *Alpinia nutans* and *Marram Grass*, *Ammophila arenaria*, are other plants which have been found to yield paper. The last named is a native of Great Britain, and is largely employed as a sand-binder on our coasts.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Oriental Trees in Southern Scotland.—The Almond tree has fruited in my garden this season for the first time for many years, and some of its fruits, very rarely seen in Scotland, have developed to an almost abnormal size. *Magnolia Watsoni*, a beautiful and intensely fragrant native of Japan (which was originally contributed to my interesting collection of Eastern trees by Sir Harry J. Veitch), after blooming profusely in June and part of July, flowered again in October like a floral after-thought of Nature.—(REV.) DAVID R. WILLIAMSON, *Kirkmaiden Manse, Wigtownshire, N.B.*

The Mild Winter.—On looking round the garden to-day (December 15) I find *Galanthus cilicicus* well out, also a particularly fine form of *G. Whittalii*. *Eranthis hyemalis* has been in flower, in a sheltered spot, for quite ten days, as has also *Cyclamen ibericum*. Primroses are peeping out all over the place, while *Iris Tauri* opened yesterday in a cold house. This is, surely, phenomenally early, especially as the bulbs are home-grown, not imported. Ever since the beginning of November, too, *Iris stylosa* has given bounteous bloom. It is a puzzling mystery to me that I see this beautiful and welcome flower in so few gardens; everybody should try to grow it.—F. HERBERT CHAPMAN.

Camellias in the Open in South-West Scotland.—There are a few gardens in the South-West of Scotland in which the Camellia does well out of doors, and among these may be mentioned Mr. Robinson-Douglas' garden at Orchardton, Castle Douglas, and Captain Hope's garden at St. Mary's Isle, Kirkcudbright. Both are in sheltered, early districts by the sea. These Camellias seem to require to be established in the open for some time before they flower, and to have them really beautiful they must have shelter. The writer knew of old plants in an exposed nursery which gave flowers for years, but which were too exposed to do any real good. These were a few miles from the sea.—S. ARNOTT.

Greenhouse Eupatoriums.—The different greenhouse Eupatoriums cannot be regarded as a showy class of plants, yet some of them are decidedly pretty, and what is of considerable importance is the fact that they flower during the late autumn and winter months. There are several kinds, of which the best known are *E. riparium* and *E. weinmannianum*, also met with as *E. odoratissimum*, but from my point of view (though, of course, opinions vary) the best of all of this section of Eupatoriums is that generally grown under the name of *E. petiolare*, but of which the correct one is said to be *E. Purpusi monticola*. This is of free growth, and will form a good bushy plant, anything from 2 feet to 4 feet in height. The flower-heads, which are over half an inch across, are somewhat suggestive of Double Daisies. They are, when first expanded, of a pale bluish tint, but become whiter afterwards. These flower-heads are borne in loose corymbs, and from these a succession is kept up for some time. For use in a cut state *E. petiolare* is of considerable service, as the neat, pretty flowers well bear close inspection, and they last well in water. Added to this they have a pleasing but by no means powerful fragrance. For the New Year the dwarf-growing *E. vernale* comes in. The flowers of this are white. Later

comes the purplish lavender-coloured *E. ianthum* and the deeper-tinted *E. atrorubens*.—H. P.

Snow and the Germination of Seeds.—The letter of your correspondent Mr. S. Arnott on page 622, issue December 14, is very interesting. Undoubtedly the soil is warmer under a covering of snow than when exposed to the keen winds which we often experience in the early part of spring; moreover, the temperature of the soil under the snow is more uniform, and seeds which have, previously to the fall of snow, begun to germinate ever so slightly continue to progress, while those in the uncovered borders are checked, and in the entire absence of snow and while the weather alternates between severe cold and mildness germination is checked. Farmers generally welcome a covering of snow for their Wheat while severe weather prevails, as the plants always make rapid progress when the thaw comes. We know how efficacious a covering of snow is in protecting plants during a frosty spell. Seeds

the rate of half an ounce to a little less than one gallon of water. Use the pure monosulphide.—GEORGE GARNER.

The Tulip Tree (*Liriodendron tulipiferum*).—This is one of the largest and most distinct exotic trees grown in this country. It is said to have been introduced during the seventeenth century. The Tulip Tree must have been planted fairly frequently in bygone days, as fine specimens 70 feet to 100 feet or a little more are by no means uncommon, scattered here and there about the country. It belongs to the Natural Order Magnoliaceæ. In North America, the native home of the tree, it is known as the Saddle Tree, the shape of the leaves somewhat resembling a saddle. The flower resembles the Tulip; hence the popular name of Tulip Tree. In summer the leaves have a fresh green appearance, changing in autumn to a lovely golden yellow hue. The flowers, which appear during June and July, are light green in colour, with a broad orange band

A FLOWERING SPRAY OF THE TULIP TREE, WHICH IS WELL ADAPTED FOR PLANTING NOW AS AN ISOLATED SPECIMEN.

germinate more quickly under any light covering than in an entirely uncovered border.—B.

Injury from Chrysanthemum Rust.—I have never heard anyone say that the rust on Chrysanthemum leaves was injurious to the health of persons working among them. The plants grown by your correspondent Mr. Frank W. Sargeant, referred to on page 622, issue December 14, must have been very badly affected. The rust is a fungus growth, and may be very poisonous. Your correspondent gives medical authority for the statement that he and his foreman were suffering from blood-poisoning; but unless the skin was broken I fail to see how the rust could have done much harm. Furthermore, much depends upon the state of the blood and general health. Rust on Chrysanthemum leaves should never be allowed to affect the plants after the cutting stage. It is quite easy to exterminate it by sponging or dipping the young plants in a solution of sulphide of potassium at

encircling the bottom of the flower near the base. The blooms of the spray illustrated are 2 inches deep and 3 inches across. There are six petals and three reflexed light green sepals, between thirty and forty anthers, and a thickened spike-like ovary in the centre. Imported seeds form the readiest means of increase, for though trees in this country produce apparently good seeds, I have not heard of any success in raising them. The Tulip Tree has the reputation of only flowering freely when the specimens reach a good size. The long spell of hot, sunny weather last year has presumably somewhat varied this rule, for in a Surrey garden a vigorous young specimen 20 feet in height has been flowering freely.—A. O.

FORTHCOMING EVENT.

January 7, 1913.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster, S.W.

HORTICULTURE IN 1912.

A BRIEF REVIEW.

THE present number of THE GARDEN marks the close of the year 1912, a year that has been of more than usual interest and significance to those who delight in gardening. In most business houses it is the custom to take stock at least once a year, so that those responsible for the management may know exactly how they stand. Profits or losses are calculated, failures and successes noted, and on the results thus obtained plans for the future are based. In much the same way, though with, perhaps, a less strict or accurate investigation, the wise gardener will review the year that is now about to close, and in so doing will bring to mind many lessons that have been learned in the prosaic university of practical experience. More often than not the best lessons are taught us by failures, for these naturally impress themselves upon our minds even more than do the brilliant successes that may be achieved, and goad us on, as Bruce of old, to try, try, try again.

The art of gardening can never stand still. In common with other pursuits of our daily life, progress becomes more rapid every year, progress that is leading us none knows whither. That we are but on the threshold of important and far-reaching developments is patent to all who take an active interest in the scientific investigation of plant-life. Electrification of the atmosphere, soil sterilisation, plant-breeding on Mendelian lines, the investigations of graft hybrids and plant diseases and pests, are all as yet in their infancy. What their ultimate value to the practical gardener will be it is impossible to say. Yet they must all tend to one great and glorious issue—the advancement of horticulture. The establishment by the Government of a diploma of Horticulture is, from an educational standpoint, a big step in the right direction, as are the grants from the Development Fund to various institutions for the investigation of plant diseases and pests, and the most suitable fruits and crops for various purposes.

Speaking generally, the year has been a generous one to gardeners. Crops of nearly all kinds have been good. Not for many years have there been such bounteous gatherings of Apples and Pears, while the Nut crop has been a record one. Roses have flourished amazingly, and as we write there are still a few stray blooms to cheer us. Daffodils and Tulips, Sweet Peas and Carnations, have all been present in abundance, and insect pests have, if anything, been less troublesome than of yore.

In other directions the year 1912 has been a memorable one. The great exhibition, so successfully held in the Chelsea Hospital Grounds during the closing days of May and the early part of June, will go down to posterity as a prominent landmark in the world of horticulture. Acknowledged on all sides to be the finest exhibition ever seen in this or any other country, the International Show of 1912 demonstrated to the whole world the wonderful advance that horticulture has made in this country during recent years; the impetus it gave to rock gardening alone will be felt for many years. Never before in the history of the society have the Royal Horticultural Society's exhibitions been so large and so well attended as they have been this year. In the spring the first special Daffodil show in connection

with the society was held, and it is pleasing to be able to record that this, the premier horticultural society in the world, is in a flourishing and rapidly growing condition.

The National Rose Society, too, has done good work during the year. Its three shows, held in London and Belfast respectively, revealed to the public at large the wonderful advance that the Rose has made and is still making. Numerous novelties of gold medal quality have been shown, and although some may not, under the severe test of time, justify the high opinion of the judges, others will go down to posterity and become the La Frances or Mme. Abel Chateaux of the future. The National Sweet Pea Society, which has passed through troublous and stormy times, has now entered smoother waters, and will, we hope, settle down to carry out the useful work that awaits to be done. The disqualifications for double standards caused much heart-burning at the summer show, and taught the committee a lesson which, when turned to practical account, will obviate such disqualifications in the future.

Notwithstanding the many demands that have been made on the purses of those generously inclined, the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund have been well supported, though even now there is much more distress that needs alleviation than the funds of these deserving gardening charities will admit. Perhaps at this season of Peace and Goodwill towards all men some of our readers who have not already done so will be disposed to assist in helping, through either of the above charities, those who can no longer help themselves.

The most pleasing personal feature in the world of gardening during the year now ending was the honour of knighthood conferred on that grand old man of horticulture, Sir Harry J. Veitch. His long and strenuous life has been devoted to the art of gardening, an art that he loves so well, and it was with universal rejoicing that the news of this honour was received by all who are privileged to know him.

The foregoing are all pleasant recollections, some full of teaching and others merely reminiscent. Unhappily, in reviewing the past, the inexorable hand of Time is also brought vividly to our notice, and reminds us of many who were with us when the year commenced, but who have since passed into the Great Unknown. The Rev. F. D. Horner, the Rev. C. C. Ellison, William Baylor Hartland, Alexander Dean, William Deal, William Thomson, William Fyfe, G. W. Piper, T. Jones, George Maw and Robert Brown are among those who have made their mark in the history of horticulture, and who, alas! have fallen into a long and well-earned repose.

We close with a personal note. During the year numerous readers in all parts of the United Kingdom, as well as many countries abroad, have written us appreciative letters of our efforts to place before them each week interesting and useful information relating to the ancient craft of gardening. To all such, and also to those who from time to time have sent useful letters for publication, we tender our best thanks. That the year which is about to dawn may bring happiness and success to all our readers is our ardent wish. With them we face the future full of hope, and look with confidence for a continuance of the practical help that has been so freely and generously afforded us in the past.

GARDENING ACROSTICS.

AS announced in our issue for December 14, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize-winners in our issue of February 15, 1913. In all cases the Editor's decision must be final. The solution to Acrostic No. 2, which appeared last week, will be published, together with a list of those who have correctly solved it, next week, and the solution to No. 3, which is printed below, will be published in our issue dated January 11, 1913. For full rules governing the competition readers are referred to page 623 of our issue for December 14.

DOUBLE ACROSTIC No. 3.

First grown to please the taste; but now to please the eye.

The first letters form one of my old names and is suggested by the above—the last spell my modern one.

1. Two letters often reversed in the name of a well-known pendulous flower.
2. The generic name of the "Daisy Tree."
3. The man who so badly damaged John Evelyn's garden.
4. The author of a very large and famous eighteenth century Herbal; useful historically for its lists of plants.
5. An old but *difficult* Iris.
6. "Many nits, many pits"—an old Devon saying about winter. What is "nit"?
7. A new mauve Primula from Himalayan mountains.
8. The popular name of a genus of plants, some of which yield fine blue dye.
9. What promotes growth in plants.
10. Thistle-like in look—and reminiscent of the sea—I make a fine bold herbaceous plant.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than January 4, 1913. Mark the envelope "Acrostic" on the upper left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 1.

"CHINA ASTER."

| | | | |
|------|---|-----------|---|
| * 1. | C | HELSE | A |
| † 2. | H | ELIANTHU | S |
| ‡ 3. | I | NDIAN SHO | T |
| 4. | N | OD | E |
| § 5. | A | LDE | R |

* The Botanic Garden at Chelsea was founded in 1673. It was very famous when Miller was curator. Site of International Show, 1912. † The Sunflower is a Helianthus; so is the Jerusalem Artichoke. ‡ Indian Shot is another name for Canna—from the resemblance of the seeds to shot. It has been much improved of late years, so much so that it is now grown for its flowers, and not, as it used to be, mainly for its foliage. § The Alder grows in damp places. Its wood is used for clogs.

** Owing to the Christmas holidays, this issue had to go to press some days earlier than usual. We are therefore unable to publish the names of those who sent in the correct solution of Acrostic No. 1, but these will appear in our next issue with the names of those who have solved No. 2.

TREES AND SHRUBS.

CULTURAL HINTS ON NEW AND RARE PLANTS.

(Continued from page 635.)

TREES AND SHRUBS.

Viburnum Carlesii.—Though introduced ten or twelve years ago, this is still a very rare shrub, although the beauty of its white, pink-tinted, fragrant flowers is such as to suggest its becoming one of the most popular species. A native of Korea, it forms a shrub 2 feet to 3 feet high, with rounded, greyish leaves. Although it will grow in loamy soil, it prefers a little peat about the roots and likes a well-drained, sunny position. Cuttings may be rooted indoors during summer.

Cotoneaster bullata.—This pretty Chinese Rock-spray is of vigorous constitution and grows at least 4 feet or 5 feet high. It is conspicuous by reason of its large, dark green leaves and axillary clusters of coral red berries. A perfectly hardy shrub,

fruits, which ripen during autumn. A position in the front of a shrubbery suits it well. Any good garden soil may be used. Its long, ferocious spines are a distinct feature.

Pinus Armandi.—Lovers of conifers would do well to include this Chinese species in their collections, for it is very beautiful in appearance and as easily grown as any common Pine. Belonging to the five-leaved group, it bears some resemblance to the Blue Pine of the Himalaya (*P. excelsa*), the leaves being very similar in colour and size. A distinguishing feature, however, is its shorter and stouter cones. It is no use planting it in or about smoky towns, for, like other cone-bearing trees, it requires a pure atmosphere, and is likely to thrive best where the ground is moist though well drained.

Erica Veitchii is a hybrid Heath which was introduced a few years ago by Messrs. Veitch of Exeter. Its parents are the two South European species *E. arborea* and *E. lusitanica*, and it inherits the excellent habit and free-flowering qualities

may thrive in an inland garden if sheltered from the cold blasts of wind. The wide-spreading branches make this tree very picturesque and give to it another popular name of Parasol Pine.

The tree illustrated on this page will readily be recognised by those who visit Kew Gardens, forming as it does a landmark on the northern side of the Succulent House. It is a particularly fine example, and is said to compare very favourably with the trees in their native habitat. Attached to the tree is a tablet with the following interesting facts concerning the Stone Pine: "Native of the Mediterranean region, cultivated in England since 1548. The characteristic shape of this tree, with its wide-spreading head of branches and rugged trunk, is well known to travellers in Italy. The famous old Forest of Ravenna, which extends not far from the shores of the Adriatic for sixteen miles, consists mainly of this tree, but much of it was destroyed by the great frost of 1879. The timber is not of much value, but in Italy the tree is cultivated for its edible seeds. During the Roman occupation of Britain these seeds appear to have been imported from Italy to feed the soldiers, as remains of them are found in the refuse heaps of Roman encampments."

It is in the winter-time that the value of this and other Pines is most apparent, for at this season the dense heads of deep green foliage form a pleasing contrast to the leafless vegetation of deciduous trees. The seeds of the Stone Pine are larger than those of any other European species, and in Italy they are sold as food, to which the people show a very partial liking.

IVY AND ITS MANY WAYS.

THINGS that are extremely familiar are often apt to pass almost unnoticed. Such a one is our common Ivy; for it is only when one gives it a little careful thought, or something more than common observation, that one perceives what a wonderful and precious plant it is, and what an important part it plays in the clothing and adornment of our winter landscape. Indeed, it may truly be said that no one kind of vegetation can do so much for us when summer-leaving trees are bare.

When one is travelling about country roads in winter, Ivy is often the only green thing to be seen. The fields are brown plough, woods and hedges are bare and leafless. Even pastures and roadsides are not green, for what short grass there is, is of a dull grey colour, and partly obscured by the buff and brown of last season's bents. But any turn of the road may bring into view deciduous trees richly mantled with Ivy, a sight that rejoices the heart of any true lover of Nature's beauties. For it is in the depth of winter that the Ivy leaves are at their glossiest and that their bowery masses not only look their best, but also give the most comforting assurance of that cosy warmth and safe harbourage so friendly and beneficial to the varied forms of bird-life.

Often some handsome arch of tree-limb bending over the roadway would pass unnoticed were it not overgrown with Ivy; but the bushily-branching dark green clothing, accentuating the tree form,

THE STONE PINE (PINUS PINEA) NEAR THE SUCCULENT HOUSE AT KEW.

it is admirably fitted for the open border, and may be given a conspicuous place. Plant in good loamy soil, and increase by seeds sown in a warm greenhouse as soon as ripe.

Clematis Armandi.—This is a very beautiful species with evergreen leaves and large clusters of pure white flowers, which, individually, are $1\frac{1}{2}$ inches to 2 inches in diameter. It is a native of China, and is likely to become popular for walls, trellises and pergolas. It requires deep, rich loamy soil, and prefers a sheltered position where the branches are exposed to full sun. Propagation may be effected by cuttings, or by grafting upon roots of some other kind. The flowering-time is late April and early May. A very useful new plant.

Berberis verruculosa is a bushy Barberry growing 2 feet or 3 feet high, with shining, evergreen leaves which are dark green above and silvery beneath. Its yellow flowers are produced in pairs from the leaf-axils, and they are followed by purplish

of both. Unfortunately, it is rather tender; therefore its culture should be restricted to the warmer parts of the country. About London it thrives and flowers well, while it has also proved to possess good qualities as a pot plant.

(To be continued.)

THE STONE PINE.

(PINUS PINEA.)

WHEN it is remembered that the Stone Pine is a native of the shores of the Mediterranean, it will not be surprising to note that it is less hardy than some other members of the same genus. Even in a warmer climate than ours—on the shores of the Adriatic—exceptionally severe weather has been followed with most drastic results to the Stone Pine, as the subjoined notes testify.

Pinus Pinea shows a distinct preference for a sandy soil, and although a seaside tree, it

FLOWER GARDEN.

THE DOG'S-TOOTH VIOLET.

THE European Dog's-tooth Violet (*Erythronium Dens-canis*), while not infrequently seen in shrubberies and semi-wild parts of large gardens, seems, at least in the suburban villa garden, almost unknown. This is particularly strange, since the plant is of easy culture, delights in half shade, and when its very decorative greenish bronze, mottled foliage rises above the ground in late February or early March, surmounted by the pure pink or pinkish lavender flowers, with a chocolate zone in their centre, it is indeed singularly attractive. On bright days the petals reflex to a considerable degree, and then display the dark bluish black anthers, which form such a strong contrasting centre to the otherwise delicate tint of the blossom.

The flowers are large in proportion to the size of the plant, being frequently 2 inches or 2½ inches across, while they seldom rise more than 3 inches to 4 inches from the

ground. Why they should have been called "Violets" has often puzzled me, as they are distinctly Lily-like in formation, which is not especially remarkable seeing that they are members of the Order Liliaceæ. I believe the name "Dog's-tooth" Violet has been conferred upon them owing to the curious tooth-like shape of the bulbs.

With me they thrive almost anywhere in the alpine garden in quite ordinary gritty soil. I have them in both complete and partial shade, also in full sun, and despite the fact that they are generally considered shade plants, my experience serves to show that they flower more prolifically if the sun falls upon them to a considerable extent, though in the alpine garden the gritty soil and the proximity of stone lumps doubtless

tend to prevent them ever getting dried up. The accompanying illustration gives some idea of a group of these charming spring flowers, which gladden us at such an early time. It also illustrates my point as to how they thrive in sunlight, at least at Woodford. The spot they occupy faces full south and receives what sun there may be throughout the day. The plants have been undisturbed for some four or five years, while the last two years especially they have been better than usual.

It is, I find, a good plan to plant them deeply, say, not less than 6 inches from the surface of the soil, often deeper; indeed, such deep planting for bulbs in the alpine garden I consider most beneficial, as it allows of surface culture for other and more feeble-rooting subjects over the place occupied by the bulbs.

Woodford, Essex.

REGINALD A. MALBY.

THE MOCCASIN FLOWER.

(*CYPRIPEDIUM SPECTABILE*.)

ALTHOUGH there are several of the *Cypripediums* hardy in this country, there is none more beautiful or interesting than the Moccasin Flower, an illustration of which is given herewith. Attaining a height of from 1 foot to 3 feet, it is a handsome plant, the broad, rather hairy leaves being surmounted by flowers of rose pink and white, from one to three being borne on a stem. This *Cypripedium* needs a cool, moist, shady situation, with soil, 1 foot deep, composed of coarse peat, good fibrous loam, some coarse sand and charcoal. If planted during the late autumn months, or even at the present time if the weather is mild, the plants will soon establish themselves, providing the roots were not allowed to get dry in transit. Once planted they are best left alone. The Moccasin Flower is often used for planting in damp, shaded nooks in the rock garden, a situation for which it is admirably adapted, but it can be used with excellent results in the border providing its requirements as to shade, moisture and soil are attended to. In the more open parts of *Rhododendron* beds we have seen it flourishing, the moist peat apparently suiting it well. It is a native of the Northern United States, and was introduced to this country in 1731, but even now it is by no means a common plant.

A SMALL COLONY OF THE MOCCASIN FLOWER
(*CYPRIPEDIUM SPECTABILE*).

reminds us how often it is that trees, and especially Oaks, assume this graceful form over roads, and thereby give the impression of protective sympathy towards those who pass by. This is the more noticeable in that the Oak is not always graceful in form like the Birch or the Ash.

The small Ivy of the hedge-bank is beautiful too, in winter, and on poor soils especially, taking on wonderful colourings of brown and bronze and red, some leaves even approaching a scarlet colour. In the trailing or creeping stage, and when it first begins to climb, the leaves are of the typical five-pointed form. But as soon as it has climbed enough to make a distinct trunk, and to throw out the woody side branches that will produce flower and fruit, the form of the leaf changes to the plain shape with pointed end, only varying more or less in width. This rule, with one exception, is invariable. As long as it trails on a bank or spreads over the floor of a wood, or only begins to climb, the leaf is wide, either five or three pointed, or, at any rate, wide-shouldered; in the mature state it has none of these leaves. The exception is where, as on walls, the Ivy is clipped every year, and is prevented from making the woody side-shoots. In this case the leaves remain of the wide shape.

Other trees—for Ivy is a true tree, having a woody stem and branches—have the same way of producing leaves of two patterns. The most familiar is the Holly, though in this case leaves both prickly and smooth-sided are seen on the same tree. The *Ilex* also has the leaves prickly-edged in a young state, and plain, almost Olive-like, when older.

Ivy that is growing on walls, as already indicated, usually needs cutting back every year, otherwise it will provide too great a leverage for the wind. This is best done towards the end of March, as new growth will then be quickly made.

ROCK AND WATER GARDEN.

ROCK GARDENS IN THE MAKING.

(Concluded from page 638.)

The Effective Grouping of Alpine Plants.—

Colonising or the effective grouping of alpine plants on rockwork is the only true way of growing them; the only effective method worthy of serious consideration; the only way, indeed, in which the operator is enabled to get the least glimpse of Nature's lavish work. At its best it will of a surety be but the veriest glimpse, yet, as such, sufficient to enthuse, sufficient to spur us on to further efforts. In Nature we see a colony or group of this or that, spreading away, carpet fashion, over soil or rock, or anon forming rugged tufts as informal as one could wish. A variation of this is seen in the individual plant stretching from rock to rock, staining it, as it were, with its flowers. Then

plants, to carry the deception further, should be high up, the finals—for the moment—seedlings of a couple of years old. There should be no abrupt endings; rather should such plants bejewel the rock crevices in diverse directions, furnishing, for example, the projecting rocky ledge and continuing stream-like into the crevices beyond. Where miniature ravines are formed with this *Ramondia* as the chief ornament, care should be taken to wedge in here and there irregular pieces of rock, a plant occurring at the upper part as though intercepted in its downward progress, with others at the sides tightly tucked against the rock, and yet another under the brow of the rock, should such exist, as though this latter had tumbled over and found a resting-place for itself. In this way not only is formality avoided, but a *multum in parvo* system is set up which makes even a small rock garden a Paradise.

Free-Growing Subjects like *Saxifragas apiculata* and *sancta merit* attention apart. These and others

plant as *Saxifraga icelandica*, the peer of the Cotyledons, need not always be kept under the eye, it is seen to finer effect higher up, where a horizontal cleft of rock would be dignified and ornamented by its presence. In this direction much good may be done by making the plant fit the position as though it were made for it alone. Quite worthy of special thought are

Suitable Plants for Dryish Places, those with silky or downy leafage that never appear to such perfection with the rank and file. A typical instance occurs in the case of the Cobweb Houseleek, which, if commonplace in a way, is without equal in its own particular line. Snugly nestling at the foot of a rock, or piling itself up against some imaginary inaccessible crag, or doing similar service over stony ground, it is one of the best plants I know. It pays, too, for separating into single rosettes, pricking these out an inch or more apart over the steeper inclines to presently form rivulets, white

almost as driven snow. The smaller rosettes of the plant—the chickens—do admirably for horizontal wall crevices. Then I think too little use is made of the carpet-forming *Sedums Lydium*, *hispanicum* and its variety *glaucum*, which are capable of the most charming effects. Too small for pricking out ordinarily, the only good way I know is to rub them to pieces through a sieve, and, mixing the particles with their own bulk of sandy soil, make a sowing where required. In a season or less the rock gardener may possess himself of perfect lawns of these and similar sorts, plants which are delightful for the hottest places imaginable.

In a Final Sentence a word must be said in favour of trailing plants, those like *Androsace lanuginosa*, *Thymus lanuginosa*, *Campanula garganica*, *Polygonum vacciniifolium*, *Saponaria*, *Coronilla*, *Phlox* and *Candytuft*, which have a value of their own for the purpose indicated. A word must also be said for favouring the free use of small bits of things—*Phlox*, *Campanula*, *Saxifrage* or what you will, whether from cuttings, divisions, or seedlings, since such as these, endowed with the freshness and vigour of youth, are those which, growing into patches,

mantle earth and rock in their own inimitable way.

E. H. JENKINS.

THE SNOWDROP WINDFLOWER.

(*ANEMONE SYLVESTRIS*.)

THIS is one of the daintiest of spring flowers for either rock garden or flower border. It is not difficult to see from what source its popular appellation is derived, for, before opening, the nodding white flower-buds readily suggest its English name of the Snowdrop Windflower. The expanded flowers are also white and, it should be added, they are sweetly fragrant. It flowers in April or in the early days of May, when it is seldom more than 18 inches high. A half-shaded position seems to suit it best, but it will revel in almost any soil. It is particularly free growing, and it should be allowed plenty of room, so that its roots may ramble unchecked. Considering its many virtues, this very pretty *Anemone* should be widely cultivated.

A TALL WINDFLOWER FOR THE ROCK GARDEN (*ANEMONE SYLVESTRIS*).

there is the free-seeding subject *Primula scotica*, or *P. frondosa*, for example, seen now in their battalions, or anon in drifts, abrupt here, trickling out in isolation there, each and all object-lessons in their way, worthy of our best attention and still more worthy of imitation. In the Friar Park rock garden there are many evidences of studious work, and the rock garden enthusiast will not go far wrong if he makes a study of the coloured plate referred to in last week's issue, and takes it so far as is possible as his guide.

A First Principle of the Plant-Grouper should be informality, since even in this the planter too frequently gets into set ways, rounding or shaping his patches of things in a way Nature never does. For example, a batch of *Ramondia* may not only trickle over the nearly vertical face of a damp rock, but spread out and beyond its base, thereby suggesting that the start was made long ago high up, and the thing we now see is the result of a few generations of seedlings. In such work the older

akin are at first carpeters of the soil. Presently, however, and with such as the first named more particularly, there is an inclination to tuftedness, which lifts the centre of the plant out of touch with the soil, death ensuing to the part if the plant is not quickly dealt with. The best way of treating all such plants is to pull them to pieces periodically, replanting little tufts of rather less than two inches across freely over any available area of ground. In this way yard-wide patches of some of the freer-flowering subjects are easily obtained. The *Aizoon Saxifragas* also well repay for separating into single rosettes occasionally, and by pricking them into well-prepared soil a greater vigour, as also freedom of flowering, is ensured. One of the best of these is *S. A. rosea*, a variety richly endowed in stem as well as in flower colour. The great Pyrenean *Rockfoil* (*S. longifolia*) is the finest of the genus, inimitable for the nearly vertical faces of the rock or for the sharpest of sunny slopes with rocks around and a good root-run of soil. So fine a

THE GREENHOUSE.

THE CULTIVATION OF MALMAISON CARNATIONS.

THE mixture which I use for the layering of Malmaisons is coke or coal ashes and rough sand, at the rate of three parts ashes to one part sand, passed through a quarter-inch sieve. As a rule, layering begins here on or about August 1, and the work is done in a shallow frame. When the plants are layered, syringe and keep them fairly close for a week, after which admit a moderate circulation of air day and night. The practice which I adopt is to tilt the sashes of the frame on their sides, thus allowing a small space at the bottom and top of the sashes to admit air and to circulate it evenly. I like to allow three weeks from the time of layering before the rooted shoots are severed from the plants. After severing, the layers are much better left for another five or six days before lifting and potting. During the period the layers are in the frame a most watchful eye is necessary, and attention must be given to the watering, as the mixture soon becomes dry. A good supply of water may be given without any risk, and wherever soft water is available, the same should be applied.

Potting Rooted Layers.—

Three-inch pots are used, and are crocked with ashes or lime-rubble. The mixture for potting consists of loam, rubble, sand, a little peat when obtainable, and a light dusting of coal soot. No leaf-mould is used, owing to eelworms being in it. The potting should be carried out to a [degree of firmness. When the batches of layers are potted—and] that is generally the end of the first week in September—they are stood in a cold frame about an inch from the glass, syringed, and shaded lightly for a few days if the weather is bright. I always grow the plants with a good circulation of air passing among them, the sashes being raised on blocks about three inches high.

Plants for Late Blooms.—

A large batch of Malmaisons in full bloom is always required for Goodwood Race Week; that is, generally, the last week in July. This is late for them to be in flower in the South of England, and the plants require special treatment. A week after the layers are potted, a large batch is stopped hard back. Soon the young plants break into growth, and throw up from five to eight growths. The plants are generally very well rooted by the second week in October, and are then potted on into 6-inch pots. That is the final potting for the first season. They are staged in a low, span-roofed house, with a free circulation of air, and a little heat in the pipes to keep the atmosphere dry. Here the plants

remain until the end of July of the following year, when the blooms are cut for use. The potting mixture at this stage ought to be heavier than that used for the layers when potted into 3-inch pots; something like four parts of loam, one part of lime-rubble, three parts of peat and sand, and a dusting of soot. Let the soil be in good condition before starting, so that the plants may be potted very firmly, as this is one of the secrets of success. When the plants are potted firmly, they go over a much longer period after being watered, and in the dark days of winter are much better kept on the dry side. The tissues of the whole plants become quite

are kept cool, and bloom at the end of July of the next year.

Rust Disease.—Regarding the rust on the Malmaisons, I have had a great deal of trouble. Three years ago, about the last week in November, I cut away all the parts that were infested with rust. I repeated this treatment during the winter months. In March, when the days were brighter, I started experimenting with salt. First of all, I used 1oz. of agricultural salt dissolved in three gallons of soft water; with this I sprayed the plants twice a week, but increased the quantity of salt each time. When the amount of salt reached 5oz.,

which I dissolved in the above quantity of water, I kept to that strength; and I have found during the past three years that spraying the Malmaisons with salt water at the above strength not only keeps the plants clean, but also invigorates their growth. The Malmaison disease, or spot, may also be kept under a great deal by the use of sulphate of potash. This should be applied to the plants (when being watered) regularly once a week, at the rate of 1oz. to one gallon of water. Should blooms be cut from plants treated thus and used in glasses for decorations, the water in the glasses may require more frequent changing than usual, as the sulphate that has been taken up into the blooms has an effect upon the water. When a batch of flowering plants requires pushing a little, 1oz. of nitrate of soda in three gallons of water, when the Malmaisons are watered, may be used with good results. Malmaisons required for winter blooming need an airy house with a night temperature ranging from 50° to 55°, according to the weather.

A. ALLARDICE.

Goodwood House, Chichester.

A SILVER-TIPPED VARIETY OF THE NORFOLK ISLAND PINE (ARAUCARIA EXCELSA SILVER STAR). A UNIQUE PLANT FOR GREENHOUSE OR ROOM DECORATION AT THIS SEASON.

THE SILVER-TIPPED NORFOLK ISLAND PINE.

(ARAUCARIA EXCELSA SILVER STAR.)

THE Norfolk Island Pine is particularly well known in this country by virtue of its ornamental uses, either as a greenhouse or as a room plant. Unfortunately, it is not hardy, but when well grown in tubs or large pots it becomes a very desirable plant so long as it does not attain proportions too large for its surroundings.

A great deal of interest has lately been centred upon a variety of this Araucaria having remarkable white tips to its growths, both lateral and terminal. The effect upon an otherwise normal plant is very striking, more especially as the Araucaria is so beautifully symmetrical. Looking down upon the horizontally spreading branches, the white tips at once suggest the name of the variety, viz., Silver Star.

At the end of the growing season these silvery white tips turn to the normal green colour of the plant, but with growth renewed it again assumes its silver starred appearance.

hard under this treatment, and are far better able to withstand the ravages of the rust that is so prevalent in the Southern Counties. The flowers are not so large from these stopped plants, although much more numerous.

Potting Old Plants.—Some plants may not throw up flowers, and these are the best to pot on for the second year, as they are stocky in habit. The best furnished plants are potted on into 9-inch pots the second week in August. I also recommend the staking of these plants as soon as possible, as then there is not so much harm done to the roots as when the staking is left until the spring. These plants

TWO OF THE FIRST ENGLISH FLOWER BOOKS.

THEIR AUTHORS AND CONTENTS.

(Continued from page 643.)

LITTLE is known of Rea beyond what can be gathered from the hints and facts which are to be found in his book "Flora seu de Florum Cultura." I suggested that the writer of his life in the "Dictionary of National Biography" was hardly justified in describing him as a market-gardener in face of the fact that he always refers, as far as he himself is concerned, to planting and gardening as a recreation or diversion. I might have added as an additional reason for my doubt that throughout the whole book he never once suggests that he has any of the plants he mentions to sell himself; but, on the contrary, seems to hint once or twice that they may be obtained in nurseries about London and elsewhere. I am sorry I am unable to offer any solution. If any readers of THE GARDEN can do so, I hope very much that they will send a note about it to the Editor who, I am sure, will only too gladly publish it. I think it will be best to say what I have to say about the "Flora" at once and leave the life of Gilbert to follow in my third article, so that it may not be separated from my description of his book.

The "Flora" was, as far as is known, the only book ever written by John Rea. Its title to fame rests on its being the first work of any importance in the English language which was entirely written from the standpoint of a garden—perhaps I ought to say "of a garden of pleasure." It is wholly horticultural and, for the first time in history, the spirit of the Herbal is altogether absent.

A second factor consists in its being the work of a man who knew what he was writing about. He had been, he tells us, a planter for forty years, and very many of the flowers that he mentions he had at one time or another grown himself. The first edition was published in 1665. It is small folio size and is divided into three parts: "Flora," Part I.; "Ceres," Part II.; and "Pomona," Part III. The frontispiece is not so elaborate as was then the fashion, but it is nevertheless in sympathy with the tone of the age, inasmuch as it is allegorical and represents the goddesses after whom the different parts of the book are named.

A preface to the reader; two letters to his patrons, Lord Gerard and Sir Thomas Hanmer; and several pieces of very fulsome poetry serve as an introduction to the more serious business of how to "make, plant, preserve and keep both Fruit and Flower gardens furnished with the choicest Plants, Flowers and Fruits that will endure the extremity of our long Winters, . . . how to set, make grow, increase and preserve each particular, as also for the raising of new varieties, . . . learned from my own practical experience."

Rea did not think much of the illustrations in Parkinson's "Paradisus," "such artless things being good for nothing, . . . for did his Flowers appear no fairer on their stalks in the Garden than they do on the leaves of his book, few Ladies would be in love with them, much more than they are with his lovely Picture." Accordingly he will have none, and all we find are "some Draughts for Flower gardens." The first edition had such "favourable Acceptance" that he published in

1776, with the assistance of that ingenious and worthy person, Sir Thomas Hanmer, a second impression "much amended" and "enlarged," a "multitude of rare Flowers and Fruits and divers considerable and necessary instructions and observations" being added. A third edition, or, rather, reprint, was issued in 1702. This is exactly the same as the 1676 one with the substitution of "third" for "second" on the title-page.

The first part, entitled "Flora," deals with the making and laying out a garden with flowering shrubs and trees and with bulbous and perennial plants. The opening paragraph tells us what manner of man John Rea was, and gives us the secret of his success. I must quote from it, for as it was then, so is it now, and so doubtless it always will be. "It is impossible for any man to have any considerable Collection of Noble Plants

THE FRONTISPIECE TO REA'S "FLORA."

to prosper, unless he love them: for neither the goodness of the soil, nor the advantage of the situation will do it, without the Master's affection." The results are twofold—he will take pains in their cultivation and spend money on their acquisition. A sentence which comes under the latter head would make a good motto for a nurseryman's catalogue: "To some" (obviously not to "J. R.") "he may seem no wiser that parts with forty or fifty pounds for an Horse or Hawk which must be daily fed and attended, than he that gives so many shillings for a noble Plant or beautiful Flower, that needs little of either."

One of the most striking points is the small size of the fruit and flower gardens suggested by the author: "Fourscore yards square for the Fruit and thirty for the Flower Garden will be enough for a Nobleman: but for a private Gentleman forty for the one and twenty for the other will be sufficient." Both are to be walled round,

and in the case of the latter it should be geometrically laid out. Long beds and wide walks are to run all round parallel with the walls, and in the centre there is to be a "fret," bounded with a low palisade covered with Roses, and the interior arranged after the fashion of the plans with which the book is furnished. It is to be a sort of out-of-doors conservatory, fed season by season from an outside nursery where there are hotbeds for raising tender plants and seeds, and "where many pretty Conclusions may be practised" in testing novelties. Here, too, is to be a house for "Greens and other tender plants in winter."

There are no very definite instructions about laying out the fruit garden. The walls are to be covered with "Pears, Plums, Cherries, Apricocks, Peaches, Nectarines and Vines." The ground inside is then to be covered with standard trees "at proportionable distances," betwixt which may be placed "Roses, Currans, Gooseberries, Cypress trees, Mizerions or what other Shrubs or Greens you like." There are to be beds round the walls and elsewhere (we are not told where), which may be planted with the poorer varieties of "Lillies, Martagons, Pionies, Daffodils, Tulips and other sorts" not fit to be received into the flower garden.

Of the most popular flowers of the day I will have something to say when I come to Gilbert's "Vade Mecum." So I pass on to Division II., "Ceres," which deals with "all such pretty Plants and fine Flowers as are yearly or every other year raised from seeds."

"And though those past do more excel,
Yet some perhaps, may like these well,
Since gain'd and kep't with little cost,
Two properties belov'd of most:
How they are raised Ceres will tell."

Again I must leave my comments and lists until next week. My sand is nearly run out, and I have said but little of "Pomona":

"That you may taste and know the best,
Pomona bids you to her Feast."

An orchard is mentioned as an adjunct of a well-equipped domain, and this partly accounts, I expect, for the small size of the fruit garden. Grafting is very fully gone into. Four different ways are mentioned and described in detail, e.g., (1) Grafting in the Cleft, (2) Whip-grafting, (3) by Approach and (4) by Inoculating or Budding.

Numerous varieties of Apples and Pears are mentioned. Many of the latter, we are told, came from France. Probably the part of most interest now is that which treats of Vines. Two of the horticultural marvels of the past in Britain are the cultivation of Saffron and Vineyards. One cannot help wondering if they really flourished. Does this remark of Rea's, I wonder, let in some light upon this problem? After wishing those who plant new vineyards good success, he says, "in some years they may have some encouragement, but if the Vineyards in such places hit one year to bear grapes fit to make wine, they are like to fail three for it: if they can make good Vinegar of them it is as much as I can expect from them."

I finish this with the closing words of the book. They are simple and of interest to-day:

"And for my guerdon this all I crave,
Some gentle hand with flowers may strew my grave,
And with one sprig of Bays my Herse befriend,
When as my Life, as now my Book doth end."

JOSEPH JACON.

(To be continued.)

GARDENING FOR BEGINNERS.

THE PROPAGATION OF LILIES.

THE Lilies, or, to give them their correct botanical name, *Liliums*, are for several reasons particularly suited for amateurs and beginners in horticulture. By far the greater number of kinds are perfectly hardy, and a dozen or more are adapted for cultivation in the ordinary soil of the small villa garden. Their propagation

1.—A SCALE LEAF FROM A LILY BULB WITH YOUNG BULB ATTACHED, SHOWING METHOD OF PROPAGATION FROM BULB SCALES.

is in reality an easy matter. For raising seedlings or growing bulbils in a small state a cold frame is useful, but by no means a necessity.

Sowing Seeds.—There are several methods of increase—by seeds, scales, bulbils and offsets, or by division. Sow the seeds as soon as ripe, or when they come to hand from the dealer, in well-drained pans or pots filled with light, sandy soil. Scatter the seeds thinly over the surface and just cover with a mixture of sand and fine soil. Place the pans or pots in a cold frame or plunge them to the rims in ashes, choosing a sheltered position away from the sun and cold winds in winter. The thin, grass-like growths of the Lilies may show above the soil in some instances in four or five weeks, others will take a little longer. One or two Lilies

3.—A CLUSTER OF LILIAM TESTACEUM BULBS, WHICH MAY BE DIVIDED UP FOR INCREASING STOCK.

are very erratic in their period of germination. Seeds of *L. giganteum*, for instance, if sown as soon as ripe, sometimes come up readily, while if stored they will not germinate for a year, or even two years, the seeds, though quite good, lying dormant in the soil.

Pricking-Off Seedlings.—When a couple of inches high, pricking-off about one and a-half inches apart to other pans or shallow boxes will be desirable. Prepare light, sandy soil for the seedlings, made up of equal parts loam, peat, leaf-mould and coarse sand. If no peat is at hand, use two parts leaf-mould. Return again to the cold frame till the following spring, or plunge in ashes outside as before. When plunged outside, the pans should be protected from frost with Bracken or light Aster (*Michaelmas Daisy*) stems. Galvanised roofing, or some similar material, is desirable over the pans to throw off excessive moisture when the tiny Lilies are resting. The next move for the seedlings will be a prepared bed of light, sandy soil in the garden. Some of the plants flower the second year from seeds, notably *L. tenuifolium*. The third and fourth years will see practically all in flower except, perhaps, *L. giganteum*, which may take a year, or even two years longer, but when it does flower, pushing up its huge spike 6 feet, 8 feet or more high, it is worth all the waiting.

Increasing by Scale Leaves.—The scale leaves of the bulbs, one of which is shown in Fig. 1, are sown thinly on the surface of pans in the same way as seeds and nearly covered with coarse sand. In due time tiny bulbils develop at the base of the scale leaves, as shown in the illustration. These push up thin grass-like leaves, and the subsequent treatment is then the same as for the seedlings. The scale leaves are obtained from the outsides of the old bulbs, a dozen or more from each. Too many must not, of course, be removed, or the parent bulb will be injured.

Propagation by Bulbils.—Bulbils are formed in the axils of the leaves on the stems of several species, the best-known being *L. tigrinum*, *L. bulbiferum*, *L. Brownii leucanthum* and *L. sulphureum*. Some Lilies develop bulbils, or tiny bulbs, near the base of the stem above the bulb, as shown in Fig. 2. Instances of this are *L. Henryi* and *L. longiflorum*. The bulbils should be detached from the stems in autumn and dibbled in boxes or pans of sandy soil, as recommended for pricking-off seedlings. Bulbils flower in about two years.

By Division.—The division or parting of Lily bulbs in autumn or spring is the most common method of increase. The fact that there are several bulbs in a cluster beneath the ground, such as the illustration of *L. testaceum* in Fig. 3 depicts, is apparent when several flower-stems come up from the clump in close proximity. All that is necessary is to lift the clumps, divide them up as much as possible, and replant. A thin layer of sand placed below and above the bulbs is a useful protection from excessive moisture in heavy soils.

The division of the *Madonna Lily*, when necessary, should be done in August. A goodly number of the sixty odd species of *Lilium* require prepared soil and selected positions in many gardens. There are, however, a number which will thrive and flower freely in most soils in company with the Japanese Anemones, Shasta Daisies, Asters and Phloxes. Twelve of the best of such Lilies are *L. pyrenaicum*, *umbellatum*, *Hansonii*, *pomponium*, *candidum*, *testaceum*, *chalconicum*, *croceum*, *Martagon*, *Martagon album*, *szovitzianum (colchicum)* and *tigrinum*. These will provide a succession of flowers from May to September. A. O.

THE WINTER TREATMENT OF ROSES.

Newly-planted Roses.—Especially after rough winds and in bleak situations it will be well to

2.—A BULB OF LILIAM HENRYI WITH SMALLER BULBILS FORMED AT THE BASE OF THE FLOWERING STEMS. THESE PROVIDE AN EASY METHOD OF PROPAGATION.

examine the plants, and any that have become loosened should be made firm by treading at the base. The Tea section are none too hardy in the event of severe weather, and their stems are apt to suffer near where they are worked on the stock. A little dry Bracken placed among them during cold spells will greatly protect them, or soil or ashes may be drawn up in a heap around the stem, and can be removed as the conditions permit.

Climbing Roses.—These will be much improved by having a good mulch of well-decayed manure applied at the base, and this may either be just worked in under the soil or allowed to remain on top. The plants on pillars or pergolas may be gone over when the weather permits, and old wood removed and the growths thinned and retied; but not during frosty weather, which is neither good for the plants nor the operator.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Lily of the Valley.—No garden is complete without a colony or more of this fragrant flower, and the present season, while the weather is open, affords a good time for planting. The ground needs to be well worked and enriched with farmyard manure, and if at all of a tenacious character, add plenty of road scrapings, leaf-mould or something of a lightening nature. Where space permits, a good site for making a plantation is under a north wall, and permanent beds will at this season benefit with a top-dressing of leaf-mould. The plants need shade, and will thrive remarkably well if planted under bush or pyramid fruit trees.

Agaves or Yuccas.—Where these are used for terraces, grown in tubs, care should be taken that they do not suffer from frost. The place in which they are stored need be only just frost-proof. Little water will be needed. The greatest care ought to be taken of the leaves. The spines on some are very sharp and poisonous, and are best protected by placing a cork on each.

The Herbaceous Borders.—During wet weather avoid treading on these as much as possible. The sooner the clumps are re-divided and planted, however, the better. The stronger-growing perennials will need considerable curtailing, and many may with advantage be transferred to the wild garden. Any plants that are known to be none too hardy should have a good covering of cinder ashes, and those that produce succulent shoots will also in this way be protected against slugs.

The Rock Garden.

Alpines in Pans.—Those who can devote a small quantity of glass to display these when grown will derive considerable pleasure from them, not only when in flower, but also during their various stages of growth. The pans should be well drained, filled with a suitable compost, and surfaced on the top with limestone or granite chippings. For a time, a frame where they may stand close to the glass will suffice. Water them in to settle the soil, but be sparing afterwards. Ventilate freely when the weather is mild, but protect adequately from hard frosts.

Plants Under Glass.

Cyclamen.—Assist the plants with properly-diluted farmyard manure occasionally, so as to prolong the season of flowering and also to keep them of good substance. Watering must be carefully done, and the water poured into the side of the pot and not on to the corm. When gathering the flowers, always pull them in preference to cutting them off.

Cleanliness of Plants.—Both young plants that are being grown on and those that are being used for furnishing should not be permitted to become infested in any way with insects, or at this dull season it will cause them much injury. Mild fumigations on calm nights will tend to keep them healthy.

The Shrubberies.

Planting.—While the weather permits, press forward with the work of transplanting, as frost may hold the ground tight for a considerable period. Choice specimens should be mulched and made perfectly secure against winds.

Shrubs for Winter Effect.—I have, I think, touched upon the subject of planting many of our commoner shrubs in masses for producing a warm and pleasing effect in midwinter. The beds are now revealing their beauty, and where one has the chance of doing it, irregular beds may now be formed in the wild garden or pleasure grounds, beside carriage drives, &c. Have the ground well dug or trenched, and add plenty of decaying refuse and manure. The following subjects will be found admirably adapted for such a purpose: *Spiraea Douglasii*, *Cornus alba* and the variegated form, *Salix viminalis*, *S. cardinalis* and the White-stemmed Brambles.

The Hardy Fruit Garden.

Blackberries.—The Cut-leaved Blackberry is deserving of wider culture, and may be planted in beds and allowed to trail over the ground-level or planted against trellises or fences in the garden,

The fruit of this is greatly in request for tarts and preserves, and the plants are really of little trouble. Now the old fruiting canes may be cut away and the current season's growths equalised out and tied into position or otherwise trained. Give the bed or surroundings a fork over and apply a mulch of decayed manure.

The Kitchen Garden.

Crops in Store.—These should be kept as cool as possible, excluding frost, and Onions especially should be looked over frequently to see that they are keeping soundly. A supply of Parsnips and Jerusalem Artichokes should be lifted, or a portion of the ground covered in case sharp frosts prevent digging them up.

Potatoes.—For early supplies next year the tubers for seed should be spread out singly in a light, cool structure, so that they will form good strong shoots. A few may be placed in trays and put in a forcing-house where it is not too hot, and be damped over occasionally.

Mushrooms.—Avoid too much fire-heat where this is installed, as it is fatal to their growth when abused. Keep the structure damped down, and see that the beds do not suffer by becoming too dry. Beds that have been in bearing some time will benefit by a good soaking of diluted liquid manure-water. Those out of doors must be well protected from cold.

Fruits Under Glass.

Replanting Vines.—When replanting Vines, if it is considered essential and the borders are taken out, if young canes take their place do not be too lenient with fresh material, but make up a new border not more than a yard wide after putting the drainage in perfect order, as this will suffice for the first season's growth, and an addition may then be made each year. This prevents the mass from becoming sour before the roots enter it, and is much more invigorating to the young rods. If dormant canes are to be planted, do so just before they commence to move their buds, allowing them to remain in the pots till then.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Belladonna Lily.—The foliage is now in course of growth, and though practically hardy, some means of securing the foliage from the effects of very severe frosts should be at hand. If not already done, stir the surface of the soil or scatter some fine soil among the plants. Ours grow in a dry, warm position.

Christmas Roses.—I do not recollect the several kinds ever to have been so early in blooming. *Helleborus angustifolius* was in flower towards the end of November, and *atifolius* was nearly past when the former commenced opening its flowers. The coloured species, on the other hand, have given fewer flowers than usual in December.

Seed Orders.—We now grow so many annuals in the flower garden, or at least flowers that are treated as annuals, that I find it convenient to order most of them before the end of the year, so as to have them delivered early in January. It must be remembered that quite a number of these, to be successful, must be sown early in the year and allowed a long period in a cool temperature to gain strength. Few of them bear a forcing heat, though a moderately high temperature may be allowed to hasten germination.

The Fruit-Houses.

Keeping Grapes.—It happens that late Grapes cannot always be cut, owing to lack of a Grape-room. The bunches may be preserved on the Vines—Muscats till the end of February, and late black varieties till some weeks later—but it is not to be commended, being expensive in keeping fires to dry the atmosphere, and hindering the cleaning of the Vines.

Vine-Cleaning.—This important operation should be proceeded with and finished as soon as possible. If the Vines have been free of insect pests during the growing season, nothing more will be needed than to rub off the loose bark, and clean in a more particular manner the spurred portions and scrub

them with hot soapy water. If insects have been in evidence, then the whole of the bark should be carefully scraped—not peeled—washed a few times with a strong soapy solution, and finally painted with clay reduced to the consistency of paint, to which a ninth part of tar has been added. Lime-wash all the stonework, and wash the woodwork with an insecticide. The glass should be well syringed with hot water. Remember that the Vine is peculiarly susceptible to injury from strong insecticides, even when at rest, and do not apply petroleum or nicotine to the rods.

Peaches.—Late varieties, as well as Vines, should be seen to without delay, first of all going very carefully over the trees and thinning shoots where they have been left too thickly, and shortening unripened tips to matured wood. I never find it necessary to wash or paint the wood of Peaches, but they should be thoroughly syringed or sprayed with hot water, after which lay in the shoots as straight as possible, giving each sufficient space for the leaves to develop without overlapping. Clear off the effete surface soil, and after applying some fruit manure, freshen it with some loam, as sound as can be got.

The Plant-Houses.

Rearrangements.—After the reduction of flowers consequent to the meeting of Christmas requirements, a great many Chrysanthemums will be thrown out and space found for Arums and the bulbous forced plants and Cinerarias, which are now fast coming on.

Dutch Bulbs.—In the course of the next week or so the bulk of these still plunged out of doors must be transferred to frames, where, for a few days, they should be covered with mats till inured to the change. Where rats are about, it is essential to protect Tulips, which is simply done by inverting an empty flower-pot over each pot. None of these will require water for some weeks.

Forcing the Above.—To succeed those already in flower or being forced, a large batch should be introduced into one of the pits with a temperature not exceeding 50°, in which they will come along very slowly and be fit to introduce to a hotter temperature as required. If space is limited, they will do very well in the meantime stored under the stages. After this date the earlier varieties of Narcissus will bear more heat, but, as a rule, they succeed best if not forced hard at an early stage of growth.

Gloxinias.—To flower early, a few old plants may be started, being very careful not to soak the soil in which the tubers are resting. As soon as the growths have begun to push, replot the plants, after which they will progress rapidly in a stove temperature.

Coleus thyrsoides.—The flower-spikes are now beginning to push, and a portion of the stock may be introduced into a higher temperature to hasten flowering. They like plenty of water at the root, also manure-water, so that the blue is intensified and the foliage kept a clear green.

Vegetables.

Tomatoes.—Those plants which have been grown so far in pots, with a few fruits set, may be planted in shallow beds with slight bottom-heat, in which they will now make better progress. At this time of year the stems must not be buried any deeper than they have been in the pots, and water must be administered very carefully for the next six or seven weeks. The sowing of some weeks ago should have resulted in plants ready to prick off, either into shallow boxes in light soil or singly into 2½-inch pots, the plant being dibbled in near to the side of the pot. Much heat is essential in the meantime.

French Beans.—With the clearing of houses of plants and the starting of Vines, it is usual to begin the forcing of these, where means for doing so earlier does not exist. They succeed very well in rather deep, narrow boxes, in which two rows of plants can be grown without crowding each other. One or two of the climbing varieties produce enormous crops, but it is too early to attempt these, an early dwarf variety, such as Osborne's Forcing, being more suitable. Currents of cold air from careless ventilation, and inefficient watering are certain precursors of red spider, which, once it attacks the plants, can scarcely be dis-established, and usually it is wise to throw out the affected plants.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.E.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Sopbro-Cattleya-Lælia Thisbe.—Sepals and petals a brilliant ruby crimson, lip of a deeper crimson hue, with a suspicion of purple. A really glorious piece of colouring. The flower measures nearly four inches across. From Mr. F. Monteith Ogilvie, The Shrubbery, Oxford.

Cypripedium Demeter (C. G. F. Moore × C. Earl of Tankerville).—A large flower of the dark-hued set. The petals and labellum are heavily marked with dull crimson, and the large dorsal sepal with crimson blotches, set off by a dull white margin. Shown by Lieutenant-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucestershire.

AWARDS OF MERIT.

Carnation Benora.—A pretty white-ground fancy of the perpetual-flowering set. The ground colour is peculiarly white and clear, the scarlet markings being thus rendered the more conspicuous. The variety is of American origin, and is sweetly scented. From Messrs. Stuart Low and Co., Bush Hill Park, Enfield.

Cattleya Tytius (C. Eud. × C. Octave Doin).—The flower is very large and handsome, the sepals and petals satiny pink; lip purplish red, feathered and reticulated with yellow and white. From Mr. H. S. Goodson, Fairlawn, Putney.

Cypripedium Idina (C. Harefield Hall × C. Countess of Carnarvon).—Sepals and petals light brown, suffused yellow; the huge dorsal sepal, which is 3½ inches across, is greenish yellow, copiously blotched with crimson and heavily bordered with pure glistening white. It is also of very thick texture. From Messrs. James Veitch and Sons, Limited, Chelsea.

Odontoglossum Scintillan (O. Rossi rubescens × O. wilckeanum).—The ground colour of the sepals and petals is purplish rose, blotched with crimson, and bordered with white in a most distinct manner. The lacerated lip is rosy purple in colour. From Mr. E. H. Davidson, Orchidene, Twyford.

Sopbro-Cattleya westfieldense (Cattleya labiata × Sopbro-Cattleya eximea).—A large flower, the sepals and petals of which are bright carmine. The labellum is large and of deeper carmine hue. Shown by Mr. F. A. Wellesley, Westfield, Woking.

Cypripedium Sir William Chance.—A large flower, with very broad and striking dorsal sepal, the centre of which is dull crimson and the outer portion glistening white. Shown by Mr. F. A. Wellesley.

Odontoglossum eximeum J. Lakin (O. ardentissimum × O. crispum).—One of the crimson-blotched varieties, with flowers of symmetrical shape and well placed on a sturdy stem. Shown by Mr. E. H. Davidson, Twyford.

Oncidium cinnabarina.—An interesting species with dull crimson flowers, these being borne mostly in clusters of three on a long, slender, arching stem. Shown by Messrs. Charlesworth and Co., Hayward's Heath.

Although there was no exhibition at the Royal Horticultural Society's Hall on December 17, the committees met as usual and the foregoing awards were made on this occasion.

THE NATIONAL ROSE SOCIETY.

ANNUAL GENERAL MEETING.

THE wonderful and ever-increasing interest that is taken in the Rose was manifested in an unmistakable manner by the large attendance of enthusiastic members at the annual general meeting of the National Rose Society, held at the Holborn Restaurant on Tuesday, the 17th inst. It speaks volumes for the excellent management of the council when we are able to record that very little of a controversial nature arose. The retiring president, the Rev. J. H. Pemberton, was in the chair, and, thanks to his business-like way of dealing with the proceedings, all matters of importance were promptly and thoroughly dealt with.

The annual report presented to the members by the council contains much that is interesting to keen lovers of the Rose and supporters of the society. The most encouraging feature is, we think, the great increase of membership. The total number of members now is 5,504, this being a net increase of 379 over last year, and an increase of 3,020 since the year 1907. The finance of the society is, happily, in an equally strong position. The total receipts during the year, including a balance of £488 15s. 10d. from last year's accounts, amounted to £4,076 18s. 9d., and after all expenses have been met and £250 placed to the reserve fund, a balance is left of £442 12s. 2d. The reserve fund now stands at £1,500. We mention these figures as indicative of the great period of prosperity that the society has enjoyed in recent years. As the president pointed out, this has no doubt been, to a large extent, due to the initiative taken by the council in recognising new types of Roses and providing exhibitions for and encouraging them in every way possible. Luckily for the society, the council has been, and is, composed of men who can appreciate the Rose in its many forms, and who are by no means strait-laced exhibitors and nothing else. The broad-minded policy adopted by the council might well serve as an object-lesson to some of our other special floral societies, whose sole aim seems to be to hold one or two shows annually.

The valuable publications, dealing fully with various phases of Rose cultivation, that are published by the society have also had a great deal to do with its popularity. For every lover of Roses who can exhibit at or attend the society's shows, there are fifty who are unable to do so, and to these in particular the publications offer a strong inducement to become members.

Regarding the future policy of the society there is not much to say. Judging by the report it is to be still a progressive one. For the first time in its history a spring show is to be held in London next year, the date being Thursday, May 1. This will enable members to see the best Roses for forcing, a most important point now that the cultivation of Roses under glass is so largely adopted. Then at the autumn show, to be held in London in September, the experiment of keeping it open two days is to be made. As Mr. Pemberton pointed out, Roses last some time in good condition at that season, and by keeping the show open late the first day many keen rosarians of the working-class will be enabled to visit the show and see the flowers they love so dearly. Mr. C. E. Shea was unanimously elected president for the next

two years, and it is interesting to record that this commences his third term of office in that capacity. The vice-presidents, hon. treasurer and hon. secretary were all re-elected, and forty-two members of council were also elected. Forty-six names were nominated and sent round to members, the unsuccessful candidates being the Rev. H. S. Arkwright and Messrs. W. R. Hammond, H. Robins and Captain W. J. Thorpe. Two personal items of interest that were dealt with at the meeting must be recorded. One was the granting of an honorarium of £100 to the hon. secretary, Mr. E. Mawley, V.M.H., whose services to the society are of a bounteous and comprehensive nature, and whose courtesy has endeared him to the hearts of all rosarians. The other was the awarding of the Dean Hole Memorial Medal to that grand old man of Rose raising and growing, Mr. George Dickson of Newtownards. This medal is the blue riband of the Rose world, and is only awarded for special and particularly valuable services rendered in the interests of the Rose. That it has been worthily bestowed no one will, we are sure, dispute.

So the National Rose Society enters upon another year full of hope and vigour. Whither its energies will lead us none can say, but so long as progress looms in the forefront of its policy, its work must tend for good.

FLOWERS FROM THE SUSSEX WEALD.

In our issue for October 26, page 547, we referred briefly to a most interesting lot of flowers that had been kindly sent us a few days previously by Mr. T. Comber, Nymans Gardens, Handcross, Sussex. Mr. Comber now sends the following particulars concerning some of them: "The flowers sent were gathered from plants growing against a south wall or in the border in front of it.

Cestrum (Habrothamnus) elegans appears likely to prove a success in this position. Its miserable appearance when grown in pots is usually due to insufficient nutriment, and it is always in better condition when placed in the border of a greenhouse or conservatory. The plant from which the flowers were cut was planted out about eighteen months ago in a corner formed by an east and a south wall. During last winter it was protected by a heap of ashes about its roots and a mat over its branches. Although the soft points of the shoots were killed, the plant soon put forth strong young shoots bearing large handsome leaves, and producing from August onwards large panicles of flowers much superior in depth of colour to those grown under glass.

Lathyrus pubescens, a native of the Argentine, has racemes of similar size and shape to those of *Lathyrus latifolius*, the common Everlasting Pea, but the flowers are of deep lavender colour. A coloured plate of this appeared in THE GARDEN for October 29, 1898. In spite of its great beauty and the fact that seed has been obtainable from Messrs. Barr and Sons for at least nine years, the plant is still uncommon. Although somewhat tender, it resents artificial heat, and is one of the many plants which can be most successfully grown when planted out. In January, 1911, we purchased a packet of seed, and the young plants were grown on in a cool house until May, when they were planted out at the foot of a south wall. Growing sturdily,

they soon attained a height of 3 feet. Early in the winter a few strong sticks, covered by a piece of coarse-meshed wire-netting, were placed at a distance of 6 inches from the plants, and the tops secured to the wall. This arrangement supported a mat in severe weather and prevented it from flapping against the plants. The pubescent nature of the plant causes moisture to cling to it, and some of the young growths decayed in consequence. The survivors grew away rapidly, reaching a height of 9 feet, and, beginning to flower in May, continued to do so until nearly the end of October.

Cyrilla racemiflora.—This American plant, growing in a border near a wall, was in late autumn covered with creamy spikes of flowers. We have had it in that position for several years, and the plant is about five feet in height and as much in diameter. In previous years it has been rather unsatisfactory, making soft, sappy growth late into the autumn, often blackened by frost in winter. It is, perhaps, due to the increased age of the plant and the warm, dry summer of 1911 that the display this year was due. The mixture of peat and loam in which it is planted appears to suit it.

Myrtus Luma (Eugenia apiculata).—The dark bronze green foliage of this Chilian Myrtle forms a rich setting to the large white flowers, whose incurved petals are delicately tinted with pink. In this neighbourhood it grows and flowers freely in the form of a bush, but in the South-Western Counties it assumes an upright tree-like growth. The shining black fruits are smaller, but have the same delicious flavour as those of *Myrtus Ugni*.

Late-flowering Heaths.—The vagaries of the weather this summer and the heavy rains in August do not appear to have adversely affected the above. During the last ten years I have never seen them flowering more freely, and to judge from the profusion of unopened buds, the display appears likely to continue for a long time. Especially is this the case with the lovely Dorset Heath (*Erica ciliaris*), its soft, downy shoots being covered with buds as well as rosy purple flowers. A dip in the ground with a slope to the north or north-west suits it exactly. We find it does best when lifted each alternate season and replanted rather deeply in light, sandy soil; roots are formed on the newly-buried stems and the plants grow with increased vigour.

A small Heath which flowers freely in autumn is the Galway Heath (*E. Maackii*); the short, upright part of the stems is densely covered with minute leaves. With us it grows most freely in a bed of peat in partial shade, but the rosy flowers are deepest in colour on the side exposed to the sun. Continuing to bloom until very late in the season, the Cornish Heath (*E. vagans*) makes up in quantity what it lacks in quality; its colour, dull bluish purple, is not very attractive. There are, besides the type, two varieties—*E. v. grandiflora*, a free-growing plant whose long stems are thickly set with flowers of the same colour as the type, and *E. v. purpurea*, which is undoubtedly the best. The latter is unique in that no other hardy Heath has flowers of the same beautiful purple. *E. multiflora* differs principally in its compact growth and the arrangement of its flowers, which are closely packed in dense corymbs at the end of the shoots. *E. m. albo-striata*, but white in colour, and the stamens are reddish brown instead of black; both are often sold under the names of *E. vagans* and *E. v. alba*.

The Cornish Heaths and their near allies are much the easiest to grow; any soil seems to suit them. I have even seen them growing vigorously in a stiff loam approaching clay, but it is advisable to mix leaf-mould with such soil when planting. October, November and March are the three best months for that operation."

ARTIFICIAL MANURES FOR THE GARDEN.

THE use of artificial manures is spreading, though, perhaps, rather slowly, to gardens, and flowers as well as vegetables are found to be quite capable of being improved and stimulated by means of fertilisers which were once, perhaps, solely associated with farming. "Patent manures" they are often still called, though the bulk of them are made by hundreds of manufacturers, with often but little difference in the prescription, and the common (often the most economical) kinds are proprietary articles. "Artificial" or "chemical" is, therefore, a better term.

It is with these commoner, and now well-known, sorts that I wish to deal, because, in the first place, they are so much cheaper; and, secondly, because the ingredients are known and appreciated. There are, of course, excellent patent brands—guanios and so forth—specially suitable to greenhouse and other valuable plants, and where knowledge of plant-life is lacking they are, perhaps, the safest to use, since a good return may be forthcoming, and no harm can be done except over-stimulation at times.

The reason for this is worth noting, and it lies in the fact that such manures are specially mixed to suit the varied requirements of plants, as regards the kind as well as the proportion of plant food. No ingredient necessary is omitted. They are, in fact, often what is known as "complete" manures, because they supply the three essential ingredients of plant food—nitrogen, phosphoric acid, often called "phosphates," and potash, or two of these constituents. It is, however, often only one of these that is specially required, and for this reason the commoner kinds, as remarked, are often more valuable, because there is not the waste, or, it may be, over-stimulation, which would be entailed by the use of a "complete" fertiliser containing more than is required. This being the case, let us glance at the uses to which these inexpensive and simpler manures can be put; but it must be remembered that, to use these correctly, some knowledge of plant nutrition is necessary.

Many plants—in fact, most—particularly need phosphates, because these are most lacking in ordinary soils; others are especially benefited by potash, though not so frequently as by phosphates, and all garden crops are partial to nitrogen. But in a garden in a good state of cultivation, phosphates are more likely to be deficient than nitrogen, while potash, especially if yard manure has been used, will often exist in plenty. Something, then, depends on the soil as well as on the individuality of the plant, and this is apt to be forgotten. People may rush to a nitrogenous manure for Roses and Carnations, and possibly get rust or grow too much leaf instead of bloom if the land is already rich, because nitrogen

is very apt to produce this effect if not used in moderation; or they may give lime when this has been already supplied in the shape of basic slag or bone-meal. Give nitrogenous manure where leaf is required, by all means, or to lawns; but give it to Nasturtiums, and the flowers will be mere adjuncts to enormous and numerous leaves.

Potash is useful for Vines, for Carrots and Parsnips, and, along with the other kinds, for fruit, Gooseberries especially, also for Asparagus, and especially for Onions. Kainit or sulphate of potash will supply it well.

Nitrogen is useful, generally speaking, for luxuriously-growing and leafy plants, hence it is excellent for such succulent stuff as Cabbage of all kinds, Lettuce that has not had yard manure (for this supplies enough if freely used), the grosser feeding pot plants and flowers of this kind; but it is much more expensive than phosphates or potash, and should be used with discretion.

There remain, then, phosphates, cheap, handy and useful as they are. It must not be expected, however, that they will give so immediate a return as nitrate of soda; for basic slag and bone-meal, for example, take some little while to become soluble. Phosphates give strength and vigour, and are excellent for Sweet Peas, but should then be applied in winter—say, bone-meal first, in a trench in January or February, or even earlier, followed by the more soluble superphosphate at seeding-time, or a few weeks before. I have found this to give excellent results, and the Sweet Peas may be grown year after year in the same ground if this plan is adopted.

A correspondent asks if superphosphate of lime is the same as the ordinary lime. It is very different. Ordinary lime is not really a manure, only a tonic to the soil, while superphosphate supplies phosphoric acid in an active form as well as some lime of a special kind, which will not take the place of the other kind. It should be applied in the early stages of growth, or at seeding-time, and so Carnations in bud, for example, would probably not benefit that season, and road scrapings, wood-ashes and rough lime are preferable.

Wood-ashes supply potash and lime, and such rough material as this and the above-mentioned is often better than richer manure. At any rate, it forms a useful foundation for many plants, and in a very cheap form. Soot or some superphosphate may be added to this, and all three constituents of plant-life are provided. Soot supplies nitrogen in a cheap and active form, and not too freely. It is useful enough for Asters and other plants, and is good mixed with water in a sack and tub. It may be used more freely than guanios, nitrate and other forcing and expensive manures, and is not so likely to have their effect—especially to be avoided in manuring flowers—of inducing a luxurious leaf-growth at the expense of blossom. Such, briefly, are some of the principles which underlie the use of mineral manures in gardens. GERVASE TURNBULL, F.L.S.

Winter Garden for Alexandra Park, Glasgow.—

We are informed that a committee of Glasgow gentlemen has been formed to promote an exhibition in the East End of Glasgow in the late autumn and winter of 1913, and to devote the surplus estimated to be realised to the provision of a winter garden for the Alexandra Park. The park is a favourite one and most valuable in that part of the city, so that a winter garden there would serve a very useful purpose.

HARDY ANNUALS
FOR CUTTING:

Double Scabious

Photo] **LILIAM AURATUM.** [Merrett Bros., Stroud.
Above blossoms at time of photographing, measured 14 1/2 inches across.

LILIAM AURATUM

The Golden - Banded Queen of Lilies.

Ivory white ground, richly strewn with purple studs. The centre of each petal has a broad band of yellow extending from tip to base. I offer this season a large stock of this peerless variety, which beyond question is the grandest of all the Lily family. Fully expanded the flowers measure 12 to 15 inches across, are produced abundantly, and possess a most delicious fragrance. **3 for 1/9, 6 for 3/-, 12 for 5/-; selected, 3 for 2/6, 6 for 6/6, 12 for 8/6; extra heavy giant bulbs, 1/3 each, 6 for 6/-, 12 for 10/-.** Can be potted for the greenhouse or planted in the open border at once. They are **perfectly hardy.**

GRAND SPECIOSUM LILIES.—The Speciosums are the hardiest, most robust and free-flowering of all Lilies, while in beauty they are second to none. The magnificence of their blossoms cannot be described, and they are perfectly hardy in the coldest gardens, and they are equally magnificent potted for the greenhouse.

SPECIOSUM RUBRUM (Lancifolium).—Large, wide flowers recurving more or less at the tips. Among the choicest of all Lilies, and perhaps the most robust and the most radiantly beautiful. Very fragrant and hardy. Lovely rose and white spotted crimson. **6 for 1/9, 12 for 3/-, 50 for 9/-, 100 for 17/-.**

SPECIOSUM MELPOMENE.—Words cannot describe the beauty of this variety. Frosted white, spotted, clouded and bearded with pinkish crimson. Petals deeply recurved and widely bordered. **3 for 1/3, 6 for 2/-, 12 for 3/6, 50 for 10/-, 100 for 18/6.**

LILIAM SPECIOSUM MAGNIFICUM.—This is the most beautiful variety of Speciosum rubrum recently discovered. It was thought that no Speciosum could exceed Melpomene, but this new Lily is even larger, grander, and if possible, more richly coloured. Clouded and suffused with rosy blush and spotted with rosy scarlet is to convey but a slight idea of its perfect loveliness. The deeply recurved petals are snowy white at the tip, gradually deepening in colour to the base of each petal, which is blotched with a raised moss-like fringe, which glistens like diamonds. The flower is very large. **3 for 1/6, 6 for 2/6, 12 for 4/6, 50 for 12/6, 100 for 21/-.**

MAGNIFICENT MIXED LILIES.—Embracing beautiful and distinct varieties, which, both for pot culture and for masses of colour in the open garden, are unsurpassed. They are very hardy, and grow and thrive under almost any conditions. **6 for 2/-, 12 for 3/6, 25 for 6/6.**

LILIAM TIGRINUM, fl. pl. (Double Tiger Lily).—This is a plant of stately habit, growing from 4 to 6ft high, bearing an immense number of double, bright orange-red flowers, spotted with black. **6 for 1/6, 12 for 2/6, 50 for 7/6, 100 for 14/-.**

TIGRINUM SPLENDENS (Improved Tiger Lily).—Bright orange, thickly spotted black. As hardy as an oak. **6 for 1/3, 12 for 2/-.**

ALL ABOVE CARRIAGE PAID.

AURICULAS
TO BUY NOW

MRS. GARDNER, F.R.H.S., PRIORY HOUSE, STROUD 26th SEASON.

Known all over the World where Plants, Bulbs and Trees can be sent. Thousands upon thousands of Testimonials for Quality, Packing, Freshness and Safe Arrival.

A FEW TESTIMONIALS JUST RECEIVED, WORTHY TO BE WRITTEN IN LETTERS OF GOLD.

J. B. HOUGHTON, Esq., Runcorn, writes, April 13th: "Plants to hand in good order and condition. I must congratulate you on the excellent way the goods were packed. It reflects very great credit on those responsible for the work."

Mrs. GLOSSOP, Whitechapel Manor, S. Moltou, writes, April 16th: "Many thanks for plants. They arrived quite beautifully packed, and are now all planted, and look as fresh as if they had never been removed."

J. WILDT, Esq., "The Limes," Gravesend, writes, April 4th: "Plants arrived this afternoon. I am delighted with them. They are strong, sturdy, and in the pink of condition, splendidly packed, and beautifully fresh. I have come to the conclusion after all where to buy my stock."

The above original letters can be seen in my office, and thousands of similar ones, Gained by Sheer Merit and Superlative Value.

WHAT MORE CAN BE SAID OF ANY PLANTS OR TREES? WHY RISK DISAPPOINTMENT?

Why bother with Stocks, Asters, and other Annuals, which only last a few months, when you can purchase at a mere nominal price Hardy Perennial Plants, which will increase and last a lifetime?

HARDY PERENNIAL AND HERBACEOUS PLANTS

are those whose foliage dies to or near the ground each autumn, coming forth again with renewed vigour the following spring. There are yet but few who secure the best results from open-air gardening, while anyone with a few rods of ground may enjoy a beautiful and permanent flower garden by planting these herbaceous or perennial plants; their first cost is the only cost, as they increase in size and beauty from year to year. The varieties described will succeed each other and give flowers from each spring until cut down by frost in autumn, and make the garden a source of unflagging interest. With slight attention to their selection, varieties may be had for any condition of soil: wet, dry, sunny or shady—there are plants for all.

COLLECTION OF PLANTS for sunny borders, shady borders, rockery, Tall Plants for back of borders, or Dwarf Plants for front of borders, 5/-, 10/-, 15/- and 21/-. Packed free and carriage paid. Also Collection for Greenhouse, 2/6, 5/-, 10/-, and 15/-, carriage paid.

These collections will be found wonderful value, and have given hundreds of my customers something more than mere satisfaction; they have been delighted.

TRITOMA UVARIA GRANDIFLORA (FLAMING TORCH OR RED-HOT POKER PLANT).—A splendid hardy summer and autumn flowering plant, producing magnificent spikes of rich orange-red flowers. A large specimen is very beautiful, with its many long, narrow, recurved leaves, which are crowned in midsummer and autumn with long crowded spikes of fiery tubular flowers, borne high above the foliage on stiff ramrod-like stalks. At a little distance the close heads of flaming orange and red flowers are very striking, and have earned the plant the common name of "Red-hot Poker." 3 for 1/3; 6 for 2/-; 12 for 3/6.

THE HARDY CRIMSON SPIRÆA.—This lovely dwarf Spiræa appears to be but little known, yet its merits deserve extensive cultivation; it is perfectly hardy, and flowers till late in the autumn. The flowers cover the path in dense clusters, and have a soft feathery appearance, which makes them extremely attractive and beautiful. A bed or border of these make a beautiful show, and take care of themselves year after year. Having a good stock I offer cheap. All two years old, grown in the open ground. 6 for 1/9; 12 for 3/-; 25 for 5/6; 50 for 10/-.

PENTSTEMON BARBATA.—Superb spikes of splendid coral red bloom; doubtless one of the finest hardy perennials that can be grown, it produces an effect that is brilliant but refined, and the graceful beauty of the plant adds much to its charms. 6 for 1/6; 12 for 2/6.

SPECIAL OFFER, MIXED CARNATIONS.—All strong autumn rooted layers, to bloom abundantly this year. Having lost the names and got several lots mixed up; these are from my splendid collection of yellow, crimson, white, scarlet, pink, purple and white, etc. Many amongst this lot worth from 1/- to 2/6; 6 for 2/-; 12 for 3/6; 25 for 6/6.

FOR TREE STRAWBERRY AND THE LOVELY BRUGMANSIA KNIGHTII, see page iii. last week.

ALL PACKED FREE AND CARRIAGE AND POSTAGE PAID TO YOUR DOOR.

New Catalogue of Delicious Fragrant Japanese Pæonies, Lilies, Carnations, Giant Flowering Clematis, and other Glorious Hardy Climbers and Herbaceous Plants in bewildering variety, Gratis and Post Free.

AN
EASILY-GROWN
CLEMATIS

MRS. GARDNER, F.R.H.S., PRIORY HOUSE, STROUD

26th SEASON.

Known all over the World where Plants, Bulbs and Trees can be sent. Thousands upon thousands of Testimonials for Quality, Packing, Freshness and Safe Arrival.

26th SEASON.

J. B. Houghton, Esq., Runcorn, writes, April 13th: "Plants to hand in good order and condition. I must congratulate you on the excellent way the goods were packed. It reflects very great credit on those responsible for the work."

Mrs. Glossop, Whitechapel Manor, S. Molton, writes, April 16th: "Many thanks for plants. They arrived quite beautifully packed, and are now all planted, and look as fresh as if they had never been removed."

Mrs. Griffiths, Sedlescombe Road, St. Leonards-on-Sea, writes, May 4th: "Mrs. Griffiths wishes to thank Mrs. Gardner for the splendid plants sent, and for the very generous quantity, they were beautifully packed and arrived in excellent condition."

The above original letters can be seen in my office, and thousands of similar ones, gained by sheer merit and superlative value. WHAT MORE CAN BE SAID OF ANY PLANTS OR TREES? WHY RISK DISAPPOINTMENT?

LILIUM AURATUM

The Golden-Banded Queen of Lilies.

Ivory white ground, richly strewn with purple studs. The centre of each petal has a broad band of yellow extending from tip to base. I offer this season a large stock of this peerless variety, which, beyond question, is the grandest of all the Lily family. Fully expanded the flowers measure 12in. to 15in. across, are produced abundantly, and possess a most delicious fragrance. 3 for 1/9, 6 for 3/-; 12 for 5/-; selected, 3 for 2/6; 6 for 4/6; 12 for 8/6; extra heavy giant bulbs. Can be potted for the greenhouse or planted in the open border at once. They are perfectly hardy, and when planted among Roses, any odd nooks round the lawn, or to fill up gaps in the herbaceous border, will reward you with blossoms in autumn that nothing else can equal. When thoroughly established they throw up 70 to 80 gigantic flowers on a spike.

Mr. Eddas, gardener, Widworthy, writes, April 7th: "I am sending order for more Auratums. I took first prize with those I had from you last year."

MAGNIFICENT MIXED LILIES.—Embracing beautiful and distinct varieties, which, both for pot culture and for masses of colour in the open garden, are unsurpassed. They are very hardy, and grow and thrive under almost any conditions. 6 for 2/-; 12 for 3/6; 25 for 6/6.

Mrs. Fry, Tunbridge Wells, writes, April 15th: "I am sending you another order for Lilies. Those I had last year were very lovely, and so much admired."

Mrs. Barrett, Wolverhampton, writes, May 4th: "The Lilies I had from you last season were very beautiful and greatly admired by all."

CLEMATIS DAVIDIANA.—This is a lovely species of Clematis, growing in bush from 3ft. or 4ft. high, and yielding through the summer great panicles of lovely blue flowers, which are exceedingly handsome and very fragrant. The foliage is large and luxuriant, and the plant is, all in all, one of exceptional beauty. It is perfectly hardy in any locality, and blooms profusely when only 1ft. high. This lovely bush Clematis will be a rare attraction in any garden or border. Plant out splendidly now. Bargain price, 3 for 2/-; 6 for 3/6; 12 for 6/-.
For special offer of Hybrid Gladiolus and the famous Blue Gladiolus, see page iii. last week. All above Packed Free and Carriage Paid.

SPECIAL OFFER, MIXED CARNATIONS.—All strong autumn rooted layers, to bloom abundantly this year. Having lost the names and got several lots mixed up; these are from my splendid collection of yellow, crimson, white, scarlet, pink, purple and white, etc. Many amongst this lot worth from 1/- to 2/6; 6 for 2/-; 12 for 3/6; 25 for 6/6.

CRIMSON CLOVE CARNATIONS.—The true old delicious spice-scented variety, now very scarce. Healthy, well-rooted plants, 3 for 1/3, 6 for 2/3, 12 for 3/6.

A GLORIOUS LARGE YELLOW CARNATION, hardy, free-flowering, vigorous growing; finest yellow in cultivation. 3 for 1/6, 6 for 2/3, 12 for 4/-.

HYBRID PENTSTEMONS.—For grand display in border, plant some of my new hybrid Pentstemons, which are now rich in variety of colour, in size almost equal to glloxinias, and have superbly splashed and mottled throats; they are quite hardy, and bloom the whole season. 6 for 2/-; 12 for 3/6.

HARDY OUTDOOR CHRYSANTHEMUMS.—Every body likes these: splendid colours; grand for cutting in autumn; perfectly hardy. Grand, well-rooted plants. Succeed anywhere planted out now. 6 for 1/3; 12 for 2/3; 25 for 4/-. Give armfuls of glorious blossoms for cutting when flowers are scarce in autumn.

Miss Coxhead, Newbury, writes, May 1st: "The Chry" santhemums I got from you last year gave me great pleasure and satisfaction."

HYBRID PYRETHRUMS, or Hardy French Marguerites.—Large, handsome flowers, of many rich and beautiful colours, including white, cream, pink, cardinal, and many other shades to rich crimson. Never fail to give pleasure wherever planted. 6 for 1/6; 12 for 2/6.

DOUBLE PYRETHRUMS, Rose-du-Barri.—A Superb Pink variety, very hardy and free-flowering. 3 for 1/3; 6 or 2/-; 12 for 3/6.

THE BLUE SPIRÆA (Cariopteris).—A lovely blue hardy perennial, covered with a mass of blue flowers all the season. Certain to become very popular, and be grown by thousands when known. These plants were a sight not readily forgotten last year, the drought and heat just suiting it. It really belongs to the Verberna family, and the foliage has that peculiar all-spice kind of fragrance liked by all. 3 for 1/6; 6 for 2/6; 12 for 4/-. Now best time to plant. Try a bed of these for a change and you will be delighted.

COLLECTION OF PLANTS for sunny borders, shady borders, rockery, Tall Plants for back of borders, or Dwarf Plants for front of borders, 5/-, 10/-, 15/- and 21/-. Packed free and carriage paid. Also Collection for Greenhouse, 2/6, 5/-, 10/-, and 15/-, carriage paid.

HELIOTROPE LORD ROBERTS.—Magnificent rich dark blue variety, deliciously fragrant, grand for greenhouse or bedding. 6 for 1/3; 12 for 2/-; 25 for 3/6. Grand hardy plants from outdoors.

HYBRID PENTSTEMONS.—For grand display in border, plant some of my new Hybrid Pentstemons, which are now rich in variety of colour, in size almost equal to Glloxinias, and have superbly splashed and mottled throats; they are quite hardy and bloom the whole season. Grand large plants. Bargain price, 6 for 1/9; 12 for 2/9; 25 for 5/- 100 for 17/6.

ICELAND POPPIES.—Perennials, but bloom first year. Very handsome and graceful, and particularly desirable, because they furnish us with a colour hitherto lacking in these flowers. The yellow and orange shades are particularly fine, and the white is very pure. 6 for 1/3; 12 for 2/-.

POTENTILLA CRIMSON QUEEN.—A true perennial, and magnificent for summer bedding; beautiful blossoms of deep rich velvety crimson, blooming the whole summer. Having a grand stock, I offer at less than half price. 12 for 1/6; 25 for 2/9; 50 for 5/-.

PENTSTEMON BARBATA.—Superb spikes of splendid coral red bloom; doubtless one of the finest hardy perennials that can be grown, it produces an effect that is brilliant but refined, and the graceful beauty of the plant adds much to its charms. 6 for 1/6; 12 for 2/6.

Another Grand Bedding Plant.
VIOLA MAUVE QUEEN.—This is a delightful shade of colour, soft, elegant, and extremely beautiful; plants simply a mass of blossom all the season. 12 for 2/-; 25 for 3/6; 50 for 6/-.

MRS. CHICHESTER.—Another lovely Viola, cream with heliotrope border, large bold upstanding blossom. King of the Blues, most brilliant of all blue Violas. Both above same price as Mauve Queen.

Also Violas in the following colours: light blue, dark blue, yellow, crimson and cream, with heliotrope border; either colour, 2/- doz.; 25 for 3/6; or all colours, mixed, 1/9 doz.; 25 for 3/-.

Mrs. GARDNER, F.R.H.S., PRIORY HOUSE, STROUD

CHRYSANTHEMUMS, Outdoor, Early flowering.—Why grow old, inferior kinds? Thousands of fine plants (not scraps) for immediate planting, in finest large-flowering recent varieties, varied lovely colours, named, 2/- doz.; 25 for 3/6; 50 for 6/-; 100 for 10/6; without names, 50 for 3/6; 100 for 5/-. Grand Value. New varieties gratis with every order. This splendid new 1911 set of 20 fine plants, correctly named, 6/-, free; two each, 10/6; Alan, Brightness, Bronze Goacher, Helena, Cherry, Bella McNeil, Beauty, Crimson Grunnerwald, Galatea, Orange Queen, Novelty, Gertie Gosney, Orion, Climax, Vulcan, Perfection, Verona, Grosvenor, Brighton, Reindeer.—E. COLNETT, 61, Wyndham Crescent, Cardiff. (Twenty-first season.)

A BEAUTIFUL
CLIMBING ROSE.

Brugmansia Knightii.

Produces the sweetest and most delicious fragrance of any flower on earth.

Called also Angels' Trumpets and Wedding Bells. One of the grandest hard-wooded plants I know of, and easy to grow. It grows several feet high, and is quite bushy. The foliage is large and tropical, and its bloom—how shall I describe what words cannot picture? Imagine a little bush three feet high, and with 20 or 30 pendulous blooms open at once; great creamy-white blooms, 11in., 12in., or 13in. long, and 8in. wide, of a texture resembling thick fluted satin. Imagine these creamy trumpets pouring fragrance forth till the air is heavy with sweetness. Imagine all this, then remember the blossoms last for days in perfection, and that new buds are constantly coming on; it is quite as easy to grow as a geranium or fuchsia, and requires the same treatment. A good plant in the garden during the summer is the talk of the neighbourhood. STOCK LIMITED.

Strong plants, one or two years old, **5** -, **7 6** and **10 6** each.

Strong plants grown this season **2 6** each.

Can be grown in greenhouse all the year round, or planted out for the summer.

NOW BEST TIME TO POT OR PLANT OUT.

ALL PLANTS SENT WITH BALL OF EARTH. NO CHECK.

Read what Mr. LEIGHTON, Kilmarnock, says about this glorious plant:—"I am delighted to tell you how beautiful the Brugmansia has been in the greenhouse. During spring it flowered abundantly, having 27 blossoms out at one time. Then I put it outdoors for the summer, where it has been blooming all the time, and had 30 blossoms out at once."

LILIUM AURATUM. The Golden-Banded Queen of Lilies.

Ivory white ground, richly strewn with purple studs. The centre of each petal has a broad band of yellow extending from tip to base. I offer this season a large stock of this peerless variety, which, beyond question, is the grandest of all the Lily family. Fully expanded, the flowers measure 12in. to 15in. across, are produced abundantly, and possess a most delicious fragrance. 3 for 1 9; 6 for 3 -; 12 for 5 -. Selected, 3 for 2 6; 6 for 4 6; 12 for 8 6; extra heavy giant bulbs. Can be potted for the greenhouse or planted in the open border at once. They are perfectly hardy, and when planted among Roses, any odd nooks round the lawn, or to fill up gaps in the herbaceous border, will reward you with BLOSSOMS IN AUTUMN THAT NOTHING ELSE CAN EQUAL. When thoroughly established they throw up 70 to 80 gigantic flowers on a spike.

Mr. EDDAS, gardener, Widdoworth, writes, April 7th: "I am sending order for more Auratums. I took first prize with those I had from you last year."

MAGNIFICENT MIXED LILIES.

Embracing beautiful and distinct varieties, which, both for pot culture and for masses of colour in the open garden, are unsurpassed. They are very hardy, and grow and thrive under almost any conditions. 6 for 2 -; 12 for 3 6; 25 for 6 6.

Mrs. FRY, Tunbridge Wells, writes, April 15th: "I am sending you another order for Lilies. Those I had last year were very lovely, and so much admired."

Mrs. BARRETT, Wolverhampton, writes, May 4th: "The Lilies I had from you last season were very beautiful and greatly admired by all."

Photo, Merrett Bros., Stroud.

BRUGMANSIA KNIGHTII.

Giant Flowering Gladiolus!

THE GLADIOLUS is the most satisfactory, the most desirable, and the most popular of all garden bulbs. Nothing else of the kind costs so little, and nothing else grows and blooms so readily for anybody and everybody, in any soil or climate. It is, in short, the most satisfactory garden flower, thriving and blooming, as it does with the least care and attention, and makes a display which for brilliancy and beauty of colouring few bulbs can equal and none surpass. The Gladiolus is to the flower garden what bread is to man, "The staff of life."

NOW FIRST OFFERED BY ME. GOLDEN VALLEY STRAIN OF GIANT FLOWERING NEW AND IMPROVED HYBRIDS.

The quality of these magnificent Hybrid Gladiolus has by great care and selection been immensely improved, and the Golden Valley Mixture will be a great advance in spite of spike and individual flowers, substance, freedom of growth; and the many new shades and splendid forms that will appear among them—far more beautiful and intensely deep, rich colours than anything that has hitherto been seen in the finest Gladioli. This new type is exceptionally free-flowering, producing bold, massive spikes, with unusually large blossoms of great substance and exquisite colours. No garden should be without these stately and noble flowers. Incomparably brilliant and majestic, and so easy of culture that they will grow in any position and in all soils and situations, producing glorious effects in absolutely endless combinations of the most brilliantly magnificent colours imaginable, ranging through all the known shades, and embracing many quite novel and intensely beautiful floral developments. Grand for exhibition. 6 for 1 6; 12 for 2 6; 25 for 4 6; 50 for 8 6; 100 for 16 -. A few EXTRA GIANT BULBS of this grand new strain, 6 for 2 -; 12 for 3 6.

Extract from "Garden Life."—"There is an extra fine sort, known as the Golden Valley strain, which reaches a height of 4ft. or 5ft., and bears spikes of blooms over 2ft. in length, the individual flowers frequently measuring 7in. to 9in. These new and improved hybrids possess the further merit that they are very free-flowering, and of intensely rich and brilliant colours."

THE MOST FAMOUS GLADIOLUS OF ALL IS MY BLUE GLADIOLUS.

"Amateur Gardening" says: "The colour is grand." Not a pale, weak, or washed-out blue, but true, deep, rich blue, of such sterling merit as to cause a sensation wherever grown or shown. It is a colour absolutely distinct. The flowers are large and bold; and so beautiful as to be absolutely peerless amongst Gladioli. Perfectly hardy, and should be planted in the open border at once. **NOW REDUCED IN PRICE, SO THAT ALL MAY GROW THIS GLORIOUS GLADIOLUS.** 3 for 2 6; 6 for 1 6; 12 for 8 -.

See page ii. last week for other grand bedding plants, etc. Everything packed free and carriage paid.

Grand New Michaelmas Aster.

BEAUTY OF COLWALL.

NOW FIRST OFFERED BY ME.

The first double variety. Flowers perfectly double, of a very pleasing shade of lavender, produced in great freedom on stout erect stems about 4ft. high. It is of robust constitution and a good grower, and requires no staking or tying to keep in position. Awarded a first-class certificate by the Royal Horticultural Society. 1 6 each; 3 for 4 -; 6 for 7 6.

A Remarkable Plant.—LIATRIS PYCNOSTACHYA (Kansas Gay Feather, Blazing Star, etc.)

It begins to bloom at the top of the spike, going downwards progressively, and remains in bloom for quite two months. It is a true perennial, and will increase and last for years. 3 for 1 6; 6 for 2 6 (usual price 1 - each).

HARDY OUTDOOR CHRYSANTHEMUMS.

Everybody likes these; splendid colours; grand for cutting in autumn; perfectly hardy. Grand, well-rooted plants. Succeed anywhere planted out now. 6 for 1 3; 12 for 2 3; 25 for 4 -. Give armfuls of glorious blossoms for cutting when flowers are scarce in autumn.

GIANT-FLOWERED HYBRID CLEMATIS.

The Clematis I offer this season are exceptionally fine, strong plants, two years old. For covering walls, trellises and verandahs, old trees, etc., they have scarcely an equal, and certainly no superior. Huge blooms as large as tea saucers, and of the most brilliant colours imaginable, from pure white to rich crimson. Bargain price, 3 for 2 6; 6 for 4 6; 12 for 7 6. All different colours; usual price, 18/- to 24/- doz.

PENTSTEMON BARBATA.

Superb spikes of splendid coral red bloom; doubtless one of the finest hardy perennials that can be grown, it produces an effect that is brilliant but refined, and the graceful beauty of the plant adds much to its charms. 6 for 1 6; 12 for 2 6.

VIOLETTAS.

MRS. GARDNER, F.R.H.S., PRIORY HOUSE, STROUD. 26th SEASON.

Known all over the World where Plants, Bulbs and Trees can be sent. Thousands upon thousands of Testimonials for Quality, Packing, Freshness and Safe Arrival. T. W. Hanshaw, Esq., Anerley, London, writes, May 16th, 1912:—"Enclosed is cheque and order for further supply of Lilies, etc. I think it is only fair to compliment you on the splendid condition of the bulbs and plants when received, and at the same time to say a word of praise with regard to the manner in which they were packed, it cannot be improved upon I am sure. It may interest you to know that my gardener says 'the plants and bulbs I get from Priory House are always miles ahead of those which I order elsewhere.'"

The above original letter can be seen in my office, and thousands of similar ones, gained by sheer merit and superlative value. **MAGNIFICENT MIXED LILIES.**—Embracing beautiful and distinct varieties, which, both for pot culture and for masses of colour in the open garden, are unsurpassed. They are very hardy, and grow and thrive under almost any conditions. When planted among Roses, say odd nooks round the lawn, or to fill up gaps in the herbaceous border, will reward you with blossoms in autumn that nothing else can equal. 6 for 1/9; 12 for 2/6; 25 for 4/6.

Mrs. FRY, Tunbridge Wells, writes, April 15th: "I am sending you another order for Lilies. Those I had last year were very lovely, and so much admired."

Mrs. BARRETT, Wolverhampton, writes, May 4th: "The Lilies I had from you last season were very beautiful and greatly admired by all."

CLEMATIS DAVIDIANA.—This is a lovely species of Clematis, growing in bush from 3ft. or 4ft. high, and yielding through the summer great panicles of lovely blue flowers, which are exceedingly handsome and very fragrant. The foliage is large and luxuriant, and the plant is, all in all, one of exceptional beauty. It is perfectly hardy in any locality, and blooms profusely when only 1ft. high. This lovely Bush Clematis will be a rare attraction in any garden or border. Plant out splendidly now. Bargain price, 3 for 2/-; 6 for 3/6; 12 for 6/-.

HYBRID PENTSTEMONS.—For grand display in border, plant some of my new Hybrid Pentstemons, which are now rich in variety of colour, in size almost equal to Gloxinias, and have superbly splashed and mottled throats; they are quite hardy and bloom the whole season. Grand large plants. Bargain price, 6 for 1/9; 12 for 2/9; 25 for 5/-; 100 for 17/6.

ANTIRRHINUM.—Something new. Little Bo-Peep Antirrhinums, or the real Tom Thumb; they only grow about six inches high, and are one mass of bloom for months; white, cream, yellow, to rich blood red; and will bloom till severe frost; and start again in early spring. 6 for 1/3; 12 for 2/-.

Also Antirrhinum grandiflora, the new tall giant; monster flowers. Same price as Tom Thumb.

CACTUS DAHLIAS.—Fine large plants, lovely colours; grown from best varieties and seedlings. Bargain Price, 6 for 1/6; 12 for 2/9; 25 for 5/-.

FOR THE GLORIOUS BRUGMANSIA, GLADIOLUS, NEW ASTER, AND OTHER PLANTS OF SPECIAL

HARDY OUTDOOR CHRYSANTHEMUMS.—Every body likes these; splendid colours; grand for cutting in autumn; perfectly hardy. Grand, well-rooted plants. Succeed anywhere planted out now. 6 for 1/3; 12 for 2/3; 25 for 4/-. Give armfuls of glorious blossoms for cutting when flowers are scarce in autumn.

Miss COXHEAD, Newbury, writes, May 1st: "The Chrysanthemums I got from you last year gave me great pleasure and satisfaction."

THE BLUE SPIRÆA (Cariopteris).—A lovely blue hardy perennial, covered with a mass of blue flowers all the season. Certain to become very popular, and be grown by thousands when known. These plants were a sight not readily forgotten last year, the drought and heat just suiting it. It really belongs to the Verbena family, and the foliage has that peculiar all-spice kind of fragrance liked by all. 3 for 1/6; 6 for 2/6; 12 for 4/-. Now best time to plant. Try a bed of these for a change and you will be delighted.

HELIOTROPE "LORD ROBERTS."—Most fragrant and delicious bedding variety, rich dark blue, dwarf, compact habit, the very finest of all bedding heliotrope on account of its exceedingly free flowering habit. Fine sturdy plants from the open. 6 for 1/3; 12 for 2/-; 25 for 3/6.

GRAND BEDDING VIOLAS.—Most superb colours, splendid sturdy plants, full of buds, will be a mass of blossom all the season. 12, 1/9; 25 for 3/-. Very scarce this season.

NEW MAMMOTH "PRIORY STRAIN" OF PANSIES. now offered for first time; same price as Violas; colours of indescribable beauty.

COLLECTION OF PLANTS for sunny borders, shady borders, rockery, Tall Plants for back of borders, or Dwarf Plants for front of borders, 5/-, 10/-, 15/- and 21/-. Packed free and carriage paid. Also Collection for Greenhouse, 2/6, 5/-, 10/-, and 15/-, carriage paid.

THE MOST FAMOUS GLADIOLUS OF ALL IS MY BLUE GLADIOLUS.—Amateur Gardening says: "The colour is grand." Not a pale, weak, or washed out blue, but true, deep, rich blue, of such sterling merit as to cause a sensation wherever grown or shown. It is a colour absolutely distinct. The flowers are large and bold; and so beautiful as to be absolutely peerless amongst Gladiolus. Perfectly hardy, and should be planted in the open border at once. NOW REDUCED IN PRICE, SO THAT ALL MAY GROW THIS GLORIOUS GLADIOLUS. 3 for 2/6; 6 for 4/6; 12 for 8/-. Flower splendidly this season.

OLUS, NEW ASTER, AND OTHER PLANTS OF SPECIAL ALL ABOVE PACKED FREE AND CARRIAGE PAID.

IVY GERANIUM CHARLES TURNER.—One of the very best, good grower, and brilliant colour, superb for hanging baskets in or out of doors. Grand autumn rooted plants, 3 for 1/3; 6 for 2/-; 12 for 3/-.

CAMPANULUS ISOPHYLLA.—Beautiful dwarf trailing species, with large silver-shaped flowers; splendid for suspended pots, etc., forming hanging streamers of lovely white flowers 3ft. to 4ft. long, doubtless the queen of hanging basket plants. Equally good for in or outdoors. 4 for 1/6; 8 for 2/6. Bargain.

GLORIOUS HARDY CLIMBERS.

DOUBLE MORNING GLORY (Calystegia).—Rare hardy perennial climber; one of the most beautiful climbing plants, covered all through the summer with a mass of full double pale rose flowers in the shape of double clematis flowers, often 3in. across. Remarkably fast and easy growing; excellent for trellis-work, for covering walls, verandahs, balconies, etc., grows on every soil. Sometimes called Rose Vine and Californian Rose, it will luxuriate anywhere, sun or shade, and when well established, its long vines, wreathed in a profusion of large double rose-like blossoms, produce a very telling effect. 3 for 1/6; 6 for 2/9; 12 for 5/-.

TUBEROUS - ROOTED WISTARIA (or Violet-scented Pea-flower Climber).—A choice, rare, exceedingly hardy, perennial climber, closely resembling Wistaria in vine and foliage, and having clusters of rich, deep purple flowers, which have a strong delicious violet fragrance. Plant near a trellis, tree, or any place where you may wish a climber. They grow to a great height and bloom profusely. It delights in plenty of sunshine, and those who can give it a warm south aspect will be rewarded with a rich harvest of the most delicious, fragrant blossoms; if left undisturbed they become stronger and more beautiful every year. 3 for 1/6; 6 for 2/9; 12 for 5/-.

BIGNONIA RADICANS.—The lovely trumpet flower climber; will grow 40ft. high; graceful foliage; charming clusters of scarlet and orange blossoms. 3 for 1/3; 6 for 2/-; 12 for 3/9.

TROPÆOLUM SPECIOSUM.—The grandest of all perennial climbers; delights in damp, shady situations. Once established it becomes ravishingly beautiful. It is the glory of the Scotch Highlands. Plants now established in pots. No check, merely turn out and plant. Sent in the pot. Per pot, 1/3; 3 pots for 2/6; 6 for 4/6.

MERIT, see page ii. of "THE GARDEN" May 25th.

MRS. GARDNER, F.R.H.S., PRIORY HOUSE, STROUD.

CACTI.—SILVER CUP, International Exhibition, 1912. Catalogue of Cacti and Carnivorous Plants, 47 pages, 159 illustrations, post free, 6d., which is allowed off first order. Fern list free. Five Gold Medals awarded me 1911.—ELLISON, 95, West Bromwich.

GREENTWIST

There is nothing to compete with "TUBE GREENTWIST" for tying garden or greenhouse plants and flowers.

A tube can be put in the waistcoat pocket and about 500 feet of the material drawn from it automatically without a stop or fear of tangle.

The material from which GREENTWIST is made is strong, yet soft and silky, and does not harm the plants in the least.

It is very neat—and ideal for tying chrysanthemums, carnations, and all garden and pot plants.

The tubes can be had by post (one tube 7d., two 1/1, dozen 6/3, post paid) from the Manufacturers:—

ROBERTSON, IRELAND & CO.,
 14, Victor Road, DUNOEE.

WAKELEY'S *celebrated* HOP MANURE

THE MOST PERFECT FERTILIZER
FOR GARDENS, GREENHOUSES, LAWNS, ETC.

THE ONLY RELIABLE AND COMPLETE SUBSTITUTE FOR STABLE MANURE

SCIENTIFICALLY AND CHEMICALLY PREPARED

in the form of a leaf mould, ready for use at any time in the same way, and for all purposes that stable manure is put. Goes further (1 cwt. equalling 15 cwts.), gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.

THE GARDEN states:—The difficulty of obtaining really good stable or farmyard manure is overcome by using Wakeley's Hop Manure. This supplies just the materials required for improving the condition of a soil, furnishing with needful humus, and providing the crops with the essential plant foods they require, viz.: nitrogen, phosphates, and potash. **THOUSANDS OF TESTIMONIALS. PARTICULARS POST FREE. BEWARE OF IMITATIONS; GENUINE ONLY IN OUR MARKED BAGS. AWARDED DIPLOMA AND MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.**
